

- 🚣 2 pm to 5 pm Paris time
- 4 4 sessions of XIOS and 1 session of dr2xml
- Position your avatar on the orange spot
- Lurn off your microphone
- training Q&A shared document
- 4 Groups of 2 or 3 for hands-on exercises

What will be covered in this tutorial:

Background of the XIOS project

LSCE

- Install and compile XIOS
- Use XIOS in a model
- XML syntax
- XIOS component (context, calendar, grid, axis, domain, file, etc.)

Get further with XIOS

- XIOS data distribution
- Use XIOS to read a file
- XIOS temporal filters
- How to perform data transformation in XIOS
- Activate the workflow graph in XIOS

How to improve the performance with XIOS

- Client-server mode of XIOS
- What is XIOS buffer, how it works?
- How to understand the XIOS report?
- How to parametrize XIOS?
- How to debug with XIOS?

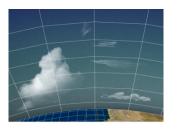

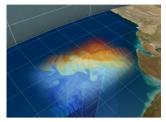

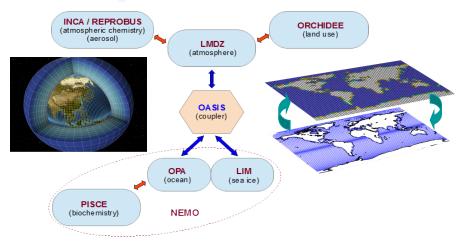

- **♣** Complex coupled model, long simulations, a lot of data generated...
- **↓** IPSL in the past Coupled Model Inter-comparison Projet phase 6 (CMIP6)
 - Since March 2018
 - 850 simulations (55000 model years)
 - 4 PB of data (1 PB publication ready data files)
 - High frequency files (3h, 6h, daily, ...)
 - Lots of metadata (title, description, unit, associated axis, ...)

Background of the XIOS project

🖶 CMIP7 next

LSCE

- CMIP3 : 24 models x 12 experiments = 39 TB (82 340 files)
- \bigcirc CMIP5 = 50 \times CMIP3
- CMIP6 = 20~50x CMIP5

3 main challenges for climate data production

- Efficient management of data and metadata definition from models
 - Human cost, errors...
- Efficient production of data on supercomputer parallel file system (HPC)
 - 1 file by MPI process?
 - Rebuild files (with different number of procs)
 - Parallel I/O efficiency? (not so efficient when many procs write to same file)
- Lomplexity and efficiency of post-treatment chain to be suitable for distribution and analysis
 - Files rebuild, time series, seasonal means...
 - Mesh re-gridding, interpolation, compression...
 - Resiliency?

Background of the XIOS project

XIOS is addressing all these challenges

- # Efficient management of data and metadata definition from models?
 - Using an external XML file parsed at runtime
 - Human readable, hierarchical
- **Lesson :** Efficient production of data on supercomputer parallel file system?
 - Dedicated Parallel and Asynchronous I/O server
- Complex and efficient post-treatment?
 - Integrate internal parallel workflow and dataflow
 - Managed by external XML file
 - Post-treatment can be performed "in situ"

XIOS is a ~12 years old software development

- End 2009 : « Proof of concept » : XMLIO-SERVER-V0
- ↓ XIOS : ~ 130 000 code lines, written in C++, interfaced with Fortran models.
 - Open Source CECILL Licence
 - Code versioning: SVN (subversion)
 - XIOS 2.5 (stable): forge.ipsl.jussieu.fr/ioserver/svn/XIOS/branchs/xios-2.5
 - XIOS trunk (dev) : forge.ipsl.jussieu.fr/ioserver/svn/XIOS/trunk
- Lused by an increasing variety of models
 - IPSL models: NEMO, LMDZ, ORCHIDEE, INCA, DYNAMICO
 - IGE (MAR), Ifremer (ROMS, MARS3D)
 - European NEMO consortium
 - MétéoFrance / CNRM : Gelato, Surfec, Arpège climat (CMIP6 production)
 - European models: MetOffice (HadGEM, MONC, GungHo), ECMWF (Open IFS, EC-EARTH)

L XIOS Team

- Yann Meurdesoif (CEA/LSCE IPSL)
- Arnaud Caubel (CEA/LSCE IPSL)
- Yushan Wang (LSCE)
- Julien Derouillat (CEA/LSCE IPSL)
- Olga Abramkina (IDRIS)

Download and compile XIOS

Download XIOS

♣ svn co http://forge.ipsl.jussieu.fr/ioserver/svn/XIOS/trunk

Compile XIOS

./make_xios

Hands-on O

Option	Value	Default	Description
arch	arch_name		Mandatory. Define target architecture
avail			Show available target architectures
prod			Compilation in production mode (default)
debug			Compilation in debug mode
full			Generate dependencies and recompile from scratch
build_dir	build_directory		Name of the build directory
job	ntasks	1	To use parallel compilation with ntasks processus
netcdf_lib	netcdf_par netcdf_seq netcdf_internal	netcdf_par	Choice of netcdf library
help			Show all available options and descriptions

XIOS Philosophy

🖶 Each time step, models expose part of their data through a minimalist interface

LSCE

Identifier (ASCII string) + address (pointer) of the data

→ Output: CALL xios_send_field("field_id",field_out)

→ Input: CALL xios_recv_field("field_id",field_in)

Less External XML File :

- Describe the incoming dataflow from models (using XML attributes)
- Describe the workflow applied to the incoming dataflow
- Describe the dataflow endpoint => output to files or returned to model

Simplicity and Flexibility

- XML file is parsed at runtime
 - Metadata, workflow and output definition can be modified without recompiling
- Hierarchical approach using strong inheritance concept
 - Attributes are inherited from parent to child
 - Avoiding redundant definition, simple and compact
 - > Very useful when you need to describe hundred's of variables

Full interactivity with models through the XIOS Fortran API

Most of the XML definitions can be completed or created from model

A minimal Fortran structure to be XIOS compliant

LSCE

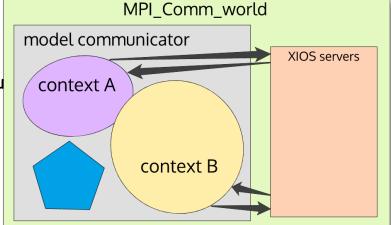

- **A** XIOS Initialization (mandatory)
 - XML files are parsed at initialization
 - CALL xios_initialize("code_id", return_comm=communicator)
 - **▶ "code_id"** must be the same for all process rank of same model
 - XIOS split the MPI_COMM_WORLD communicator between clients and servers and return the split one for client side

Context initialization (mandatory)

- CALL xios_context_initialize("context_id",communicator)
 - **"context_id"**: id of the context to bind with context defined in XML file
 - **communicator**: MPI communicator associated to the context
 - Must be the same or a sub communicator of which returned
 - at XIOS initialization
- Context initialization can be done at any time
- Different contexts can be initialized during same ru
- All XIOS calls from model are collective for the
- associated context MPI communicator

Switching to a context

- CALL set_current_context("context_id")
 - All xios fortran calls afterwards will be related to context "context_id"

XIOS Fortran interface 2/3

Complete the XML database definition

LSCE

- Set missing attribute
 - Some attribute values are known only at run time
- All attribute can be set via the Fortran API
 - CALL xios_set_'element'_attr("element_id",attr1=attr1_value, attr2=attr2_value,...)
- New child element can be added
 - All XML tree can be created from Fortran interface
 - Ex: adding "temp" field element to "field_definition" group

```
CALL xios_get_handle("field_definition", field_group_handle)
CALL xios_add_child(field_group_handle,field_handle,id="temp")
```

- Setting time step and other calendar specific attributes
 - CALL xios_define_calendar(type="Gregorian") (mandatory in fortran or in xml)
 - CALL xios_set_timestep(duration)
- Closing context definition (mandatory)
 - CALL xios_close_context_definition()
 - Context data base is analysed and processed
 - Any modification behind this point would not be taken into account and unexpected results may occur

XIOS Fortran interface 3/3

∔ Entering time loop and send data

- When entering a new time step, XIOS must be informed
- CALL xios_update_calendar(ts)
 - **ts**: timestep number
- Time step must begin to 1
- Time step 0 refers to part between context closure and first time step update
 - Only received field request can be done at time step 0
- Data can be exposed during a time step
 - CALL xios_send_field("field_id",field)
 - CALL xios_recv_field("field_id",field)
 - Sent data field would create a new flux tagged with timestamp related to the time step
 - → Data can be received only if the outgoing flux have the same timestamp to the related time step

Finalize context

- All opened context must be finalized after the end of time loop
- CALL xios_context_finalize() close the current context.

Finalize XIOS

- After finalizing all opened context, XIOS must be finalized, servers are informed, files are properly closed and performance report is generated
- CALL xios_finalize()

XIOS Hello World!

Fortran

```
SUBROUTINE hello world(rank,size)
USE xios
IMPLICIT NONE
    INTEGER :: rank, size, timestep
TYPE(xios_duration)
                       :: dtime
DOUBLE PRECISION,ALLOCATABLE :: lon(:,:), lat(:,:), field (:,:)
INTEGER :: ni, nj, ibegin, jbegin
                                                     Initialise XIOS and one context
CALL xios_initialize("client", return_comm=comm)
CALL xios_context_initialize("hello_world", comm)
CALL xios_set_domain_attr("domain", ibegin=ibegin, ni=ni, jbegin=jbegin, nj=nj)
CALL xios set domain attr("domain", lonvalue 2d=lon, latvalue 2d=lat)
                                                                           Define domain
dtime%second=3600
                                     Set time step
CALL xios set timestep(dtime)
                                     to 1 hour
                                                  Fnd of context definition
CALL xios_close_context_definition()
                                                  No more modification to
                                                  the context
DO timestep=1,96
 CALL xios_update_calendar(timestep)
  CALL xios_send_field("field", field)
                                                          Enter the time loop
ENDDO
CALL xios_context_finalize()
CALL xios_finalize()
                                       Free the context
END SUBROUTINE hello_world
                                                                                 Hands-on 1
                                       and guit XIOS
```

XIOS needs XML

XML: Extensible Markup Language

- Set of rules to define a document in a format
- Both human-readable and machine-readable

4	Tag	j : a	markup	construct	that	begins	with	"<"	and	ends	with	">	>"
---	-----	-------	--------	-----------	------	--------	------	-----	-----	------	------	----	----

- Start-tag: <.....>
- End-tag: </.....>
- empty-element tag, such as <..... />
- 4

Element : construct delimited by a start-tag and an end-tag, or consists only of an emptyelement tag

- Element: <field > </field>
- Empty-element : <field />
- May have child elements
- <field_group>
- <field />
- <field />
- </field_group>
- May have content: text between start-tag and end-tag element: <field> content </field>
 - Used in XIOS to define arithmetic's operations

LSCE

- Attributes : a construct consisting of a name-value pair (name="value") that exists within a start-tag or an empty-element tag
 - Ex: Element field has 3 attributes: id, name and unit
 - <field id="temp" name="temperature" unit="K" > </field>
 - <field id="temp" name="temperature" unit="K" />
- Left Comments: begin with <!-- and end with -->
 - <field> <!-- this is a comment, not a child nor a content --> </field>
 - "--" (double-hyphen) is not allowed inside comments. No nested comments

L XML document must be well-formed

- XML document must contain only one root element
- All start-tag element must have the matching end-tag element (case sensitive) and reciprocally
- All element must be correctly nested

XML parser

rapidxml

General XIOS-XML Syntax

XML master file must be iodef.xml

LSCE

- Parsed first at XIOS initialization
- Root element name is simulation
- Root element can only contain context type elements

Main element families: represent objects type stored in XIOS database

- context: isolate and confine models definition, no interference between them
- calendar : mandatory, 1-to-1 association with context
- scalar, axis, domain
- grid
- field
- file: input or output
- variable : define parameters for models and for XIOS parameterization

Each element family can be divided into 3 types (except for context)

- Simple elements: ex: <field />
- Group elements: ex: <field_group />
 - Can contain children simple element
 - Can contain children nested group of the same type
- Definition elements: ex: <field_definition>
 - ➡ Unique root element type
 - Act as a group element, i.e. can contains other groups or simple elements

General XIOS-XML Syntax

Each element may have several attributes

- i.e. : <file id="out" name="output" output_freq="1d" />
- Attributes give information for the related element
- Some attributes are mandatory: error is generated if attribute not defined
- Some attributes are optional but have a default value
- Some attributes are completely optional

♣ Attributes values are ASCII string, depending on the attribute, can represent :

- A character string: name="temperature"
- An integer or floating value : output_level="3" add_offset="273.15"
- A Boolean : true/false : enabled="true"
 - Fortran notation .TRUE./.FALSE. are allowed but obsolete
- A date or duration : start_date="2000-01-01 12:00:00"
 - See format later
- A bound array (inf,sup)[values]: value="(0,11) [1 2 3 4 5 6 7 8 9 10 11 12]"

General XIOS-XML Syntax

🖶 Special attribute id : identifier of the element

LSCE

- Make reference to the element
- Unique for one given kind of element
 - ➡ Elements with same id ⇒ same element (append, overwrite)
 - Be very careful when reusing same ids, not advised (no fixed parsing order)
 - Definition elements are equivalent to group elements with a fixed id
 - **⇒** Ex: <field_definition> ⇔ <field_group id="field_definition" ...>
- id is optional, but no reference to the element can be done later

XML file can be split in different parts.

- Very useful to preserve model independency, modularity
- id must be the same in both xml files
- Using attribute "src" in context, group or definition element
 - attribute value give the name of the file to be inserted in the database

Why Inheritance?

- Attributes can be inherited from another element of same family
- Hierarchical approach, very compact
- Avoiding useless redundancy

Inheritance by grouping : parent-child inheritance concept

- All children inherit attributes from their parent
- An attribute defined in a child is not inherited from his parent
- Special attribute "id" is NEVER inherited

```
<field_definition level="1" prec="4" operation="average" enabled=".TRUE.">
    <field_group id="grid_W" domain_ref="grid_W">
        <field_group axis_ref="depthw">
        <field id="woce" long_name="vertical velocity" unit="m/s" operation="instant" />
        </field_group>
    </field_group>
    </field_definition>
```

<field id="woce" long_name="vertical velocity" unit="m/s" axis_ref="depthw" domain ref="grid W" level="1" prec="4" operation="instant" enabled="true" />

4 Inheritance by reference

- Only for field, domain, axis, and scalar elements
 - → field ref
 - **domain** ref
 - axis_ref
 - scalar_ref

- Don't mix up with grid_ref!
- Source element inherit all attributes of referenced element
 - Attributes already defined in source element are not inherited (or is overwritten)

```
<field id="toce" long_name="temperature" unit="degC" grid_ref="Grid_T" enabled="true" />
<field id="toce_K" field_ref="toce" long_name="temperature(K)" unit="degK" />
<field id="toce_K" long_name="temperature(K)" unit="degK" grid_ref="Grid_T" enabled="true"/>
```

- Warning, reference inheritance is done AFTER group inheritance
- Disable attribute inheritance by setting its value to "_reset_"

Why Context?

- Context is similar to "namespace"
- Contexts are isolated from each other, no interference is possible
 - ids used inside one context can be reused in other context
- For parallelism, each context is associated with its own MPI communicator
 - No interference between MPI communicators
- Generally a context is associated to one model
 - Principle of modularity
- A model can declare more than one context

∔ Context element :

- <context>...</context>
- Must be inside of the root XML element
- Must have an id
- Contains calendar and
- other element definition

XIOS calendar

🖶 Each context must define its own calendar

LSCE

- One calendar by context
- Define a calendar type
 - Date and duration operation are defined with respect to the calendar's type
- Define starting date of the model
- Define time step of the model

Calendar type

- Gregorian : standard Gregorian calendar
- D360 : fixed 360 days calendar
- NoLeap : fixed 365 days calendar
- AllLeap : fixed 366 days calendar
- Julian : Julian calendar (leap every 4 years)
- user_defined : months and days can be defined by user (planetology and paleoclimate)

Date and Duration

- A lot of XML attributes are of date or duration type
- Operation between date and duration are strongly dependent of the chosen calendar
 - \Rightarrow Ex: date + 1 month = date + 30 day only for month 4,6,9,11

XIOS calendar

L Duration units

Year : y

Month : mo

Day : d

Hour : h

Minute : mi

Second : s

Time step : ts (related to time step context definition)

Duration format

 Value of unit may be integer or floating (not recommended), mixed unit may be used in a duration definition

⇒ Ex. : "1mo2d1.5h30s"

▶ Ex. : "5ts"

Date format

year-month-day_hour:minute:second

Ex.: "2020-11-04 10:00:00"

Partial definition are allowed. Taking into account leftmost part

Ex. "2020-11" equivalent to "2020-11-01 00:00:00"

⇒ Ex. "2020-11 12" format error (OK in some case)

Cea XIOS calendar

Date format

LSCF

- Date can be also define with a duration offset
 - Useful for defining a calendar based on standard units (seconds for example)
 - **⇒** Ex. : "+3600s"
 - Or mix: "2012-5 +3600s" equivalent to "2012-5-1 01:00:00"

Attributes for calendar

- type : define the calendar type (mandatory)
 - "Gregorian", "D360", "NoLeap", "AllLeap", "Julian" or "user_defined"
- time_origin: (date) define the simulation starting date ("0000-01-01 00:00:00" by default)
- start_date: (date) define the starting date of the run ("0000-01-01 00:00:00" by default)
- timestep: (duration) define the time step of the model: mandatory

4 Setting calendar

From XML: specific child context element: calendar

Defining an user defined calendar

- Planetology or paleo-climate can not use standard calendar
- Personalised calendar
 - Defining day_length in second (default 86400)
 - → Defining month_lengths: number of days for each month (in an array)

```
<!-- the simplified Darian calendar -->
<calendar type="user_defined" day_length="88775"</pre>
```

Or if you don't want to specify month, you need to define year length in second.

```
<!-- 300 days per year -->
<calendar type="user defined" day length="86400" year length="25920000"</pre>
      start date="2020-11 12" />
```

- ▶ In this way, the format for "date" will no longer contain "month". In Fortran interface, "month"=1
- Possibility to define leap year
 - Attributes: leap_year_month, leap_year_drift, leap_year_drift_offset
 - See XIOS user guide

Fortran interface for calendar

4 Duration

LSCE

- Fortran derived type: TYPE(xios_duration)
 - **♦** (REAL): year, month, day, hour, minute, second, timestep
 - xios_year, xios_month
 - xios_day, xios_hour
 - xios_minute
 - xios_second
 - xios_timestep

TYPE(xios_duration) :: duration duration%second = 1800 duration = 1800 * xios_second duration = 0.5 * xios hour

Half an hour

🚣 Date

Fortran derived type: TYPE(xios_date)

♦ (INTEGER): year, month, day,

hour, minute, second

TYPE(xios_date) :: date(2014,12,15,10,15,0) date%year = 2015

Date and duration operation

- duration±duration, duration*real, -duration, ==, !=, >, <</p>
- date-date, ==, !=, >=, >, <=, <</p>
- date±duration
- String conversion: xios_duration_convert_[to/from]_string,
- xios_date_convert_[to/from]_string
- Useful functions: xios_date_get_second_of_year, xios_date_get_day_of_year,
 - xios_date_get_fraction_of_year, xios_date_get_fraction_of_day

Setting calendar from Fortran interface

- CHARACTER(LEN=*) :: type
- TYPE(xios_duration) :: timestep
- TYPE(xios_date) :: start_date, time_origin
- Within single call
 - **▶** SUBROUTINE xios_define_calendar(type, timestep, start_date, time_origin, ...)
 - **type** is mandatory.
 - •
- Or with individual call
 - SUBROUTINE xios_set_timestep(timestep)
 - SUBROUTINE xios_set_time_origin(time_origin)
 - SUBROUTINE xios_set_start_date(start_date)
- calendar type must be defined at first.

Hands-on 2-1

XIOS scalar

♣ Scalar description : the scalar element <scalar />

LSCE

- **Attributes**
 - (double) value
 - (string) name
 - (string) long_name
 - (string) scalar_ref
- ♣ More often used in data transformation
 - see later

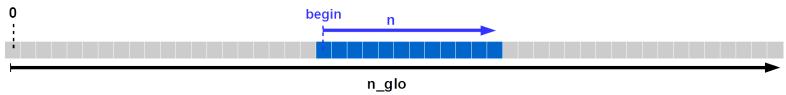

XIOS axis

- Axis description : the axielement <axis />
 - Describe 1D axis, generally vertical axis
 - CALL xios_set_axis_attr("axis_id", ...)
- Defining the global size of the axis
 - (integer) n_glo : global size
- Defining the data parallelism distribution across MPI processes
 - (integer) n : local axis size distribution
 - (integer) begin: local axis distribution beginning with respect to the global axis
 - \rightarrow C-convention, starting from 0.
 - If nothing specified, the axis is considered as not distributed.
 - Data distribution is different for each MPI process, not suitable for XML description
 - Attributes only known at run-time can be passed dynamically using the Fortran interface
 - → See section Fortran interface setting attributes

- Defining axis coordinate values and boundaries
 - (real 1D-array) value[n]
 - (real 2D-array) bounds[2,n]

Hands-on 2-2

XIOS domain

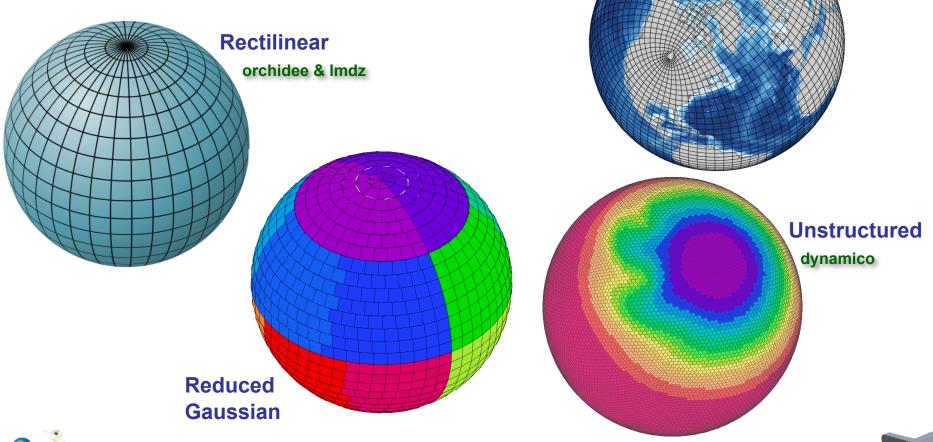

2D horizontal layer description : the domain element <domain />

LSCE

Curvilinear

nemo

- Describe generally 2D layers mapping the surface of the sphere
- Large variety of 2D domains can be described
- (string)type:
 - "rectilinear", "curvilinear", "unstructured", "gaussian"

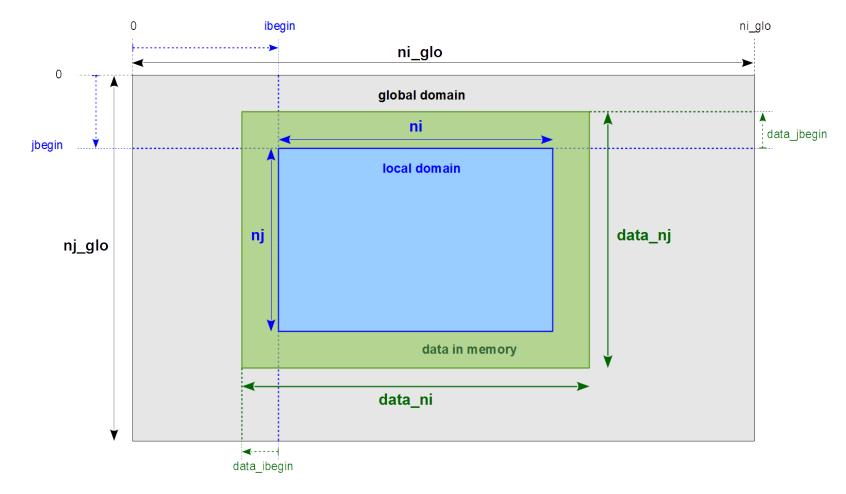

Rectilinear or curvilinear domains have a 2D description

- **LSCE**
- (integer) ni_glo, nj_glo: global domain size for each direction (longitude and latitude)
- (integer) ibegin, ni, jbegin, nj : local domain definition

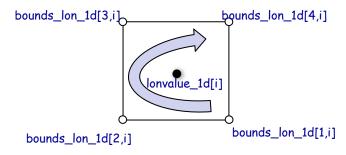

Defining coordinates

- For rectilinear domain
 - → latvalue 1d[nj]: latitude coordinates of cells
 - ▶ lonvalue_1d[ni] : longitude coordinates of cells
 - **bounds_lat_1d[4,nj]**: latitudes boundaries of cell corners
 - **bounds_lon_1d[4,ni]** : longitudes boundaries of cell corners
- For curvilinear
 - latvalue_2d[ni,nj]
 - lonvalue_2d[ni,nj]
 - bounds_lat_2d[4,ni,nj]
 - bounds_lon_2d[4,ni,nj]
- For unstructured domain
 - → (integer) nvertex: max number of corners/edges among cells
 - (double) latvalue_1d[ni]
 - (double) lonvalue_1d[ni]
 - (double) bounds_lat_1d[nvertex,ni]
 - (double) bounds_lon_1d[nvertex,ni]

Hands-on 2-3

4 Describing the mesh : the grid element <grid />

- Can describe element of dimension: 0, 1, ..., 7
- Defined by composition of scalar, axis and domain
- Empty grid is representing a scalar
- 0D : (scalar)
- 1D : (axis)
- 2D : (domain), or (axis, axis)
- 3D: (domain, axis), or (axis, axis, axis)
- ...
- recommend using element reference
- can also define element inside
- •Field geometry is provided by •the underlying mesh description
- Can be virtual

n be virtual

Hands-on 2-4

XIOS field

- The field element <field />
- Represent incoming or outgoing data flux from models
- ∔ Data can be sent or received at each time step from model through the Fortran interface
 - Sending data
 - CALL xios_send_field("field_id", field)
 - Receiving data
 - CALL xios_recv_field("field_id", field)
- 🚣 Fields geometry and parallel distribution is hosted by the underlying grid description
 - (string) grid_ref attribute : id of the grid
 - For more flexibility fields can refer to a domain
 - (string) domain_ref attributes => create a virtual 2D grid composed of the referred domain

~

- Or a domain and an axis to create a virtual 3D grid
 - domain_ref and axis_ref

```
<grid id="grid_3d">
    <domain id="domain_2d/>
    <axis id="axis_1d" />
    </grid>
...

<field id="temp" grid_ref="grid_3d"/>
```

Field data from models must be conform to the grid description

LSCE

- Fields can be declared of any dimensions in single or double precision
- But total size and data order must be the same as declared in the grid
 - Example:

- **→** Global grid: 100×50×20
- Local grid: 10x5x20
- ▶ Data in model memory: data_ni × data_nj × n_glo = 12×7×20 = 1680
- Can be declared as :
 - REAL(kind=4) :: temp(12,7,20)
 REAL(kind=4) :: temp(1680)
 REAL(kind=8) :: temp(1680)
- but data order follows the column major order Fortran convention

Field can be output to files

- Will appear as a child element of file element
- A field can appear, in multiple files
 - using the reference attribute : field_ref

```
<field_definition>
 <field id="temp"
                    grid_ref="grid_3d"/>
 <field id="precip" grid_ref="grid_3d"/>
 <field id="pressure" domain ref="domain 2d"/>
</field_definition>
<file_definition>
 <file name="daily_output" freq_output="1d">
   <field field_ref="temp" />
   <field field ref="pressure" />
 </file>
 <file name="monthly_output" freq_output="1mo">
   <field field ref="temp" />
   <field field_ref="precip" />
 </file>
</file_definition>
```

Field attributes

LSCE

- Field description :
 - ★ (string) name: name of the field in the file. If not specified, "id" will be used in place
 - **⇒** (string) long_name : set "long_name" netcdf attribute conforming to CF compliance
 - (string) standard_name : set "standard_name" netcdf attribute
 - **(string) unit**: set "unit" netcdf attribute
 - **⇒** (double) valid_min/valid_max : set valid_min & valid_max nectdf attribute
- Enable/disable field output :
 - **boolean)** enabled: if false, field will not be output (default=true)
- Precision and compression:
 - → (integer) prec : define the output precision of the field : 8->double, 4->single, 2->2-byte integer
 - → (double) add_offset, scale_factor: output will be (field+add_offset)/scale_factor
 - → (integer) compression_level (0-9): set the gzip compression level provided by netcdf4/hdf5: due to HDF5 limitation, doesn't work for parallel writing. If not set data is not compressed.
 - **(boolean) indexed_output**: if set to true, only not masked value are output.

XIOS field

∔ Field time integration

LSCF

- At each time step, data field are exposed from model (xios_send_field)
- Data are extracted according to the grid definition
- Time integration can be performed on incoming flux
- The time integration period is fixed by file output frequency (output_freq attribute)
- (string) operation attribute: time operation applied on incoming flux
 - **once**: data are used one time (first time)
 - instant : instant data values will be used
 - maximum : retains maximum data values over the integration period
 - minimum: retains minimum data values over the integration period
 - average : make a time average over the period
 - cumulate : cumulate date over the period
- Example: each day, output the time average and instant values of "temp" field

```
<file name="output" output_freq="1d">
    <field field_ref="temp" name="temp_average" operation="average"/>
    <field field_ref="temp" name="temp_instant" operation="instant"/>
    </file>
```

XIOS field

业 Time sampling management

LSCF

- Some field are not computed every time step
- (duration) freq_op attribute: field will be extract from model at "freq_op" frequency
- (duration) freq_offset attribute: time offset before extracting the field at "freq_op" frequency
- Strongly advised to set freq_op and freq_offset as a multiple of time step
- Example: for making a daily averaging, get "temp" value every 10 time step. The first value extracted will be at 2nd time step.

```
<file name="output" output_freq="1d">
    <field field_ref="temp" operation="average" freq_op="10ts" freq_offset="1ts"/>
    </file>
```

Undefined values and time operation

- Undefined values must not participate to time integration operation
 - → Set default_value attribute as the undefined value (missing value). If not defined, missing value will be 0.
 - → (boolean) detect_missing_value: for the current time step, all field value equal to default_value (undefined value) will not be taking into account to perform the time integration (average, minimum, maximum, cumulate)
- Very expensive since each value of the mesh must be tested

Hands-on 2-5

XIOS file

- Output file : the file element <file />
- L Defining fields to be written
 - File elements can contains field elements or field_group elements
 - All listed field elements are candidates for output
 - (string) field_group_ref attribute: fields included in the referred field group will be included in file

```
<field definition>
 <field_group id="fields_3d" grid_ref="grid_3d"/>
   <field id="temp" >
   <field id="precip" >
 </field group>
 <field id="pressure" domain_ref="domain_2d"/>
</field definition>
<file definition>
 <file name="daily output" freq output="1d">
   <field_group_field_group_ref="fields_3d" operation="average"/>
   <field_group operation="instant"/>
     <field field ref="temp" name="temp inst" />
     <field field ref="pressure" name="pressure inst" />
   </field group>
   <field field ref="pressure" operation="average" />
 </file>
</file_definition>
```

- Variables output as average :
 - 🗪 temp
 - precip
 - pressure
- Variables output as instant
 - temp_inst
 - pressure_inst

Cea XIOS file

Leading /disabling output

Hands-on 2-6

- Field can be enabled/disabled individually
- Enable/disable with level output
- Enable/disable all fields
 - **(bool) enabled** file attribute : if set to false, all fields are disabled
- Files with all fields disabled will not be output

🚣 File format

- For now file output format is only NETCDF
 - → Grib2 and HDF5 output format will be considered in future
- Can choose between parallel write into a single file or multiple file (1 file by xios server)
 - (string) type attribute : select output mode "one_file" / "multiple_file"
 - For "multiple_file" mode, files are suffixed with xios servers ranks
- Can choose between netcdf4 et netcdf4 classical format
 - ⇒ (string) format attribute: "netcdf4" for netcdf4/hdf5 or "netcdf4_classical" for historical netcdf3 format
 - → In "one_file" mode, use hdf5 parallel for netcdf4 format and pnetcdf for classical format.
 - Sequential netcdf library can be used in multiple_file mode
- Data can be compressed : only available with netcdf4 format (hdf5) in sequential write (multiple_file)
 - → (integer) compression_level attribute: compression level (0-9), can be fixed individually with field attribute.

XIOS variable

Setting parameters : the variable element <variable/>

- Variable are used to define parameters
- Variable can be set or queried from model
 - Could replace Fortran namelist or IPSL run.def files
- Used internally by XIOS to define its own parameters

Attributes

- (string) name : name of the attribute (optional)
- (string) type: type of the variable (optional)
 - → "bool", "int16", "int", "int32", "int64", "float", "double", "string"

∔ Setting variable values from XML

Values are defined in the content section

```
<file>
    <variable id="int_var" type="int"> 10 </variable>
    <variable id="string_var" type="string"> 10 </variable>
</file>
```

variable_definition and variable_group

🖶 Set or query value from model

Set variable: ierr = xios_setvar('var_id', variable)

Get variable: ierr = xios_getvar('var_id',variable)

Return true if 'var_id' is defined and second argument contains the read value

return false if 'var_id' is not defined and second argument value is unchanged

```
<variable definition>
  <variable id="int var" type="int"/> 10 </var>
  <variable id="string var" type="string">a string variable
</variable definition>
USE xios
INTEGER:: int var
CHARACTER(LEN=256) :: string_var
LOGICAL :: ierr
 ierr=xios_getvar('int_var',intvar)
 ierr=xios_setvar('int_var',intvar+2)
 ierr=xios_getvar('int_var',intvar) ! -> int_var=12
 ierr=xios_getvar('string_var',string_var) ! -> string var="a string variable"
```

XIOS axis data distribution

Defining how data are stored in memory

LSCE

- Data are stored in memory as Fortran array
- But data can be masked, or ghost cells are not valid data, or axis value can be compressed
- XIOS will extract only required value from memory
- Must describe valid data with attributes
- Whole data are valid by default

Masking Data (optional)

- (boolean 1D-array) mask[n] (false/zero : data masked)
- Masked data will not be extracted from memory and will appear as missing values in output files

Defining ghost cells (optional)

- (integer) data_n : size of the data in memory (default : data_n=n)
- (integer) data_begin : offset with respect to local axis distribution beginning
 - default : data begin=0
 - Negative offset: data outside of the local distribution will not be extracted (ghost cell)
 - Positive offset: data in interval [begin, data_begin] and/or [data_begin+data_n-1, begin+n-1] are considered as masked.

 O data_begin=-3 data_n=18

Cea

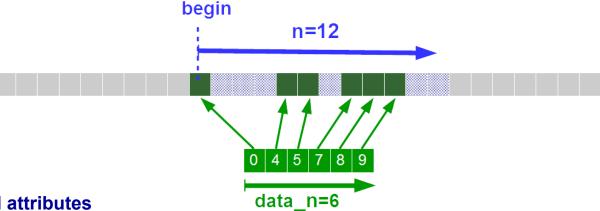

XIOS axis data distribution

Defining compressed data (optional)

LSCE

- Data can be compressed in memory (ex: land point), and can be decompressed for output
- Undefined data are considered as masked and will be output as missing value
- (integer 1D-array) data_index
 - Define the mapping between data in memory and the corresponding index into the local axis distribution
 - data_index[i]=0 map the beginning of the local distribution
 - Negative index or greater than n-1 will be outside of the distribution and will not be extracted

- Other optional attributes
 - (string) name
 - (string) long_name
 - (string) unit
 - (bool) positive: set "positive" CF attribute in Netcdf output

XIOS domain data distribution

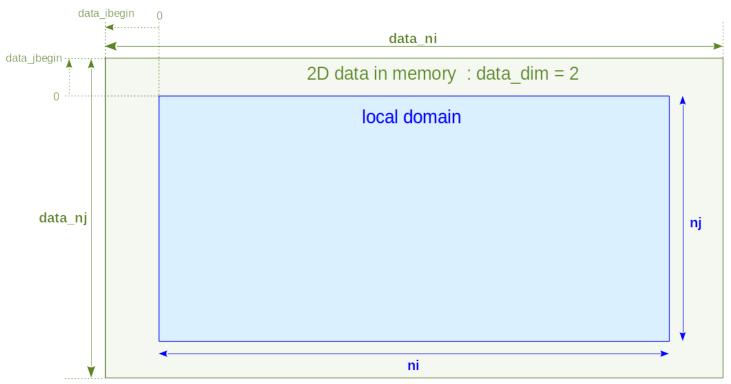

Data representation in memory: similar to 1D-axis but for 2 dimensions

LSCE

- Can be 1D-array (horizontal layer as a vector) or 2D-array
- (integer) data_ni, data_nj : size of the array dimension
- (integer) data_ibegin, data_jbegin attribute : Offset for each dimension with respect to local domain distribution beginning : may be negative or positive (default : 0)
- Example for data_dim=2, negative offsets to eliminate ghost cells

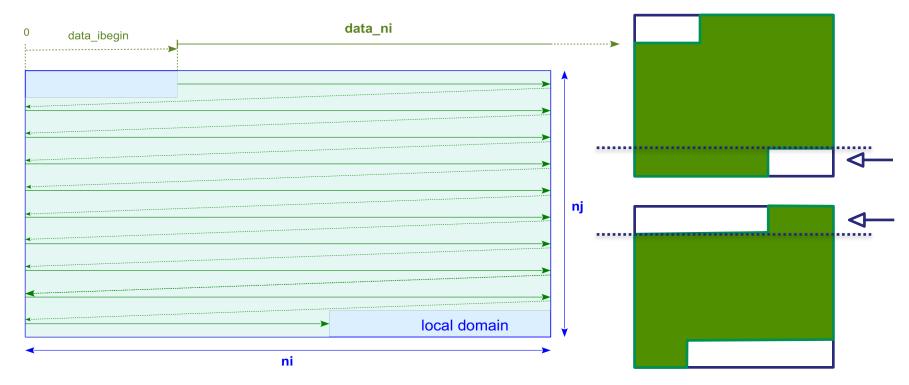

XIOS domain data distribution

- Example for data_dim=1: horizontal layer seen as a vector
- (integer) data_ni : size of the array dimension
- (integer) data_ibegin: Offset with respect to local domain distribution beginning
 - Positive offsets, local domain from different processes can overlap

1D data in memory: data_dim = 1

XIOS domain data distribution

Unstructured domain has a 1D description

- Data in memory is always a vector
 - → data dim=1

Compressed data (on "data")

- For data_dim=1 (decompressed data is a 1D-array)
 - data_i_index[data_ni]: index for decompressed local domain represented by vector
 - (exclusive with data_ibegin)
- For data_dim=2 (decompressed data is a 2D-array)
 - data_nj must be equal to data_ni
- data_i_index[data_ni], data_j_index[data_ni]: indexes for decompressed local domain represented as a 2D-array
- (exclusive with data ibegin, data ibegin)

XIOS data mask

Masking grid point individually

LSCE

- Ex. grid=(domain, axis)
 - masking one point in the 3rd axis means masking a full 2D layer in the 3d grid
- Grid point can be masked individually using the mask attribute
- Regarding of the dimensionality of mask arrays, version mask_1d to mask_7d are allowed
 - Total mask size must be equal to the local domain size
 - **⇒** Ex : <grid id="grid_3d" mask_3d="(0,9)x(0,4)x(0,19)[0 1 1 0 ... 0 1]">
 - → Or: <grid id="grid_3d" mask_1d="(0,9990)[0 1 1 0 ... 0 1]">
 - Not practical with xml. Better set mask via Fortran API.
 - O or false => masked

Hands-on 3

∔ File structure

- XIOS respects CF convention as much as possible
- One time record (unlimited dimension) by file
 - (duration) output_freq attribute : define the output frequency and the time axis
 - time_counter dimension and axis are written conforming to CF convention
- Can mix instant and average time operation
 - Axis time_instant or time_centred may be written with the associated bounds
- Fields of different grids can be in same file
 - Longitude, latitude and verticals axis are automatically written with the associate metadata following CF convention
 - Axis boundaries will be also written if available
- Some fields attributes (standard_name, long_name, unit,...) will be output as field metadata

Example of **netcdf** file output with XIOS

```
netcdf output_atmosphere_2D_HR {
dimensions:
     axis nbounds = 2:
     lon = 200;
     lat = 200 :
     time_counter = UNLIMITED ; // (30 currently)
variables:
     float lat(lat);
           lat:axis = "Y" :
           lat:standard_name = "latitude" ;
           lat:long_name = "Latitude"
          [at:units = "degrees_north";
           lat:nav model = "domain atm HR";
     float lon(lon):
          lon:axis = "X"
           lon:standard name = "longitude" ;
           lon:long_name = "Longitude";
           lon:units = "degrees_east"
           lon:nav_model = "domain_atm_HR";
     float tsol(time_counter, lat, lon);
tsol:long_name = "Surface Temperature";
           tsol:online_operation = "average";
tsol:interval_operation = "3600 s";
          tsol:interval_write = "1 d" ;
           tsol:cell_methods = "time: mean (interval: 3600 s)";
           tsol:coordinates = "time_centered";
     double time_centered(time_counter);
          time_centered:standard_name = "time"
          time_centered:long_name = "Time axis";
time_centered:calendar = "gregorian";
          time_centered:units = "seconds since 1999-01-01 15:00:00";
           time_centered:time_origin = "1999-01-01 15:00:00";
          time_centered:bounds = "time_centered_bounds";
     double time_centered_bounds(time_counter, axis_nbounds);
double time_counter(time_counter);
time_counter:axis = "T";
          time_counter:standard_name = "time";
          time_counter:long_name = "Time axis";
           time_counter:calendar = "gregorian"
           time_counter:units = "seconds since 1999-01-01 15:00:00";
           time_counter:time_origin = "1999-01-01 15:00:00" ;
time_counter:bounds = "time_counter_bounds" ;
     double time counter bounds(time counter axis nbounds);
// global attributes:
           :name = "output_atmosphere_2D_HR";
:description = "Created by xios";
           :title = "Created by xios"
           :Conventions = "CF-1.5" :
          :production = "An IPSL model";
:timeStamp = "2015-Dec-14 15:20:26 CET";
```

More on the output file

🖶 Adding specific metadata

- Using variable element <variable/>
- Variable as file child will be output as a global netcdf file attribute
- Variable as field child will be output as a netcdf variable attribute
- Example:

```
<file name="daily_output" freq_output="1d">
    <field field_ref="pressure" operation="average" >
        <variable name="int_attr" type="int"> 10 </variable>
        <variable name="double_attr" type="double"> 3.141592654 </variable>
        </field>
        <variable name="global_attribute" type="string"> A global file attribute </variable>
        </file>
```

∔ Flushing files

- File can be flushed periodically in order to force data in cache to be written
- (duration) sync_freq file attribute : flush file at sync_freq period

More on the output file

∔ Appending data to an existing file

- When restart models, field data can be appended to a previous XIOS output file
- (bool) append attribute: if set to true and if file is present, data will be appended
 - Otherwise a new file will be created
 - Default is creating a new file (append=false)

Splitting files

Hands-on 4

- In order to avoid big file, file can be split periodically
- File suffixed with start date and end date period
- (duration) split_freq : split file at split_freq period

Generating time series (CMIP requirement)

- Fields included into a single file may be automatically spread into individual files
- One field by file, file name based on field name
 - **♦** (string) ts prefix file attribute : prefix for time series files
 - ♦ (bool) ts_enabled field attribute: is set to true, field is candidate to be output as time series
 - ★ (duration) ts_split_freq field attribute: individual field split frequency (default is file splitting frequency)
- (string) timeseries file attribute (none / only / both / exclusive): activate time series output
 - **none**: standard output, no time series
 - → only: only field with ts_enabled="true" will be output as time series and no other output
 - **both**: timeseries + full file
 - **⇒** exclusive : field with ts_enabled="true" will be output as time series, the other field in a single file

Read data with XIOS

🖶 Reading data from file

- (string) mode attribute ("read" / "write"): if set to read, file will be an input
- Each time record will be read at every freq_output frequency (a little ambiguous but ...)
- Value can be get from models at the corresponding time step using:
 - CALL xios_recv_field("field_id", field)
- First time record will sent to model at time step 0 (before time loop).
- Except using freq_offset field attribute
 - Exemple: freq_offset="1ts": first record will be read at first time step and not 0

```
--- xml ---

<file name="daily_output" freq_output="1ts" mode="read" >

<field id="temp" operation="instant" freq_offset="1ts" grid_ref="grid_3d"/>

</file>

--- model ---

DO ts=1,n

CALL xios_update_calendar(ts)

CALL xios_recv_field("temp",temp)

ENDDO
```

Field with no time record will be read only once

Cea

XIOS workflow functionalities

Why Workflow?

LSCE

- Field are exposed from model at each time step
 - internally representing data flux assigned to a timestamp
- Each data flux can be connected to one or more filters
- Filters are connected to one or more input flux and generate a new flux on output
- All filters can be chained together to achieve complex operations
- All filters are parallel
- XML file describe a full graph of parallel tasks

4 Workflow entry point

- Input flux can be a field sent from model (xios_send_field)
- Input flux can be a field read from an input file (mode="read")

🖶 Workflow end point

- Output flux can be sent to servers and written to file (mode="write")
- Output flux can be read from model (xios_recv_field)
 - **▶** (bool) read_access field attribute : field read from models must set read_access="true"
 - Field read from file have automatically read_access="true"

XIOS workflow functionalities

```
--- xml ---

<field id="precip" grid_ref="grid_3d"/>

<field id="precip_read" field_ref ="precip" read_access="true" />

<fiile name="daily_output" freq_output="1ts">

<fiile name="daily_output" freq_output="1ts">

<fiile id="temp" operation="instant" grid_ref="grid_3d"/>

</file>

--- model ---

DO ts=1,n

CALL xios_update_timestep(ts)

CALL xios_send_field("temp",temp)

CALL xios_send_field("temp",temp)

CALL xios_send_field("precip",precip)

CALL xios_recv_field("precip_read",precip_read) ! Now precip_read==precip

ENDDO
```

field_ref attribute : duplicate flux from the referenced field

• For each reference to field, a new flux is created by duplicating source flux

Also, make XML inheritance

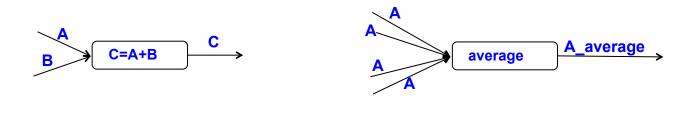

Defining filters and transformations

LSCE

Actually 3 kinds of filters

- Arithmetic filters: combine flux together
- Temporal filters: integrate flux over a period of time
- Spatial filters: transform the geometry of the incoming flux

🚣 Arithmetic filters

- Arithmetic filter can combine different flux of same timestamp with arithmetic operator or function
- All incoming flux must be on the same grid
 - Perform same operations for each grid point
- Arithmetic filter are defined in the content section of a field element
- Computed flux value will replace actual flux, even if coming from reference

```
<field id="temp" unit="°C" grid_ref="grid_3d"/>
<field id="temp_K" unit="°K" field_ref="temp"> temp+273.15 </field>
```

Specific "this" (auto-reference) keyword representing the incoming flux of the current field <field id="temp" unit="°K" grid ref="grid 3d"> this+273.15 </field>

- Arithmetic filters can be easily chained,
 - Computed flux can be reused

$$^{\bullet}C = \frac{A+B}{A*B}$$

$$D = \frac{e^{-C*D}}{3}$$

Time integration filters

- **4** Time filters of are specified with the "operation" field attribute
 - Possible value: "once", "instant", "maximum", "minimum", "average", "accumulate"
 - A new flux is generated at the end of the time integration period
- Time filter is enabled only if :
 - Field is included into a file
 - output_freq define the period over which integration is done
 - Generated flux is the sent to server to be recorded
 - Flux can be reused by an other field after time integration
 - → The @ operator : means that time integration is performed over the flux
 - The time integration period is given by value of freq_op attribute of new flux

```
<field id="temp" operation="average" />
<field id="temp_ave" freq_op="1d"/> @temp </field>
```

New flux "temp_ave" is created every day (freq_op="1day") by time averaging of "temp" flux

Chaining time filters

- Using the @ operator
- Example: compute and output the monthly average of the daily maximum and minimum of temperature and the monthly maximum and minimum of the daily temperature average

```
--- xml ---
<field id="temp"
                           operation="average"/>
<field id="temp min" field ref="temp" operation="minimum" />
<field id="temp max" field ref="temp" operation="maximum" />
<file name="monthly output" output freq="1mo" />
<field name="ave_daily_min" operation="average"
                                                   freq op="1d"> @temp min </field>
                                                   freq_op="1d"> @temp_max </field>
 <field name="ave daily max" operation="average"
 <field name="min_daily_ave" operation="minimum"
                                                   freq op="1d"> @temp
                                                                             </field>
<field name="max daily ave" operation="maximum" freq op="1d"> @temp
                                                                             </field>
</file>
--- model ---
CALL xios send field("temp", temp)
```

Chaining and combine time filters and arithmetic's filters

• Compute the time variance of a temperature field $\sigma pprox \sqrt{\left\langle T^2 \right\rangle - \left\langle T \right\rangle^2}$

```
--- xml ---

<field id="temp" operation="average"/>
<field id="temp2" field_ref="temp" /> temp*temp </field>

<file name="monthly_output" output_freq="1mo" />
<field name="sigma_T" operation="instant" freq_op="1mo"> sqrt(@temp2-@temp*@temp) </field>

</file>

--- model ---

CALL xios_send_field("temp",temp)
```

Hands-on 6

Spatial filters

LSCE

- Spatial filters may change the geometry, dimensionality and the parallelism data distribution of a flux
- Algorithms must be parallel and scalable in order to perform the flux transformation on whole allocated parallel resources of a simulation
- More filters under development

🖶 Using spatial filters

- Spatial filters are enabled when the grid of a referenced field is different of the current grid field
 - No spatial filter enabled
 - (same grid ref)

```
<field id="temp" grid_ref="grid_regular"/>
<field id="new_temp" field_ref="temp" grid_ref="grid_regular" />
```

- Trigger spatial filter
- (different grid ref)

```
<field id="temp" grid_ref="grid_regular"/>
<field id="new_temp" field_ref="temp" grid_ref="grid_unstruct" />
```

- If grid are not matching exactly, try to find a way to transform source grid into target grid
 - ➡If not possible an error is generated
 - Otherwise filter will be used

XIOS spatial filter

- To find which filter to activate, a matching is done between domain and axis composing the grid.
 - An exact matching between element do not activate filter
 - → If not matching, see if it is possible to transform the source element domain or axis into target element with a transformation.
 - Otherwise an error is generated

```
<axis id="vert_axis" n_glo="100" />
<domain id="regular" ni glo="360" nj glo="180" type="rectilinear" />
<domain id="unstruct" ni glo="10000"</pre>
                                            type="unstructured" />
<grid id="grid regular">
 <domain domain_ref="regular>
 <axis axis ref="vert axis" >
</grid>
<grid id="grid unstruct">
 <domain domain_ref="unstructured">
  <interpolate domain/>
 <domain/>
 <axis axis_ref="vert_axis" >
</grid>
<field id="temp" grid ref="grid regular"/>
<field id="new_temp" field_ref="temp" grid_ref="grid_unstruct" />
```

XIOS spatial filter

More than one filter can be implemented in same transformation

```
<axis id="vert_src" n_glo="100" />
<axis id="vert_dst" n_glo="50" />
<domain id="regular" ni_glo="360" nj_glo="180" type="rectilinear" />
<domain id="unstruct" ni glo="10000" type="unstructured" />
<grid id="grid regular">
 <domain domain_ref="regular/>
 <axis axis ref="vert src"/>
</grid>
<grid id="grid_unstructured">
 <domain domain ref="unstructured">
  <interpolate_domain/>
 <domain/>
 <axis axis_ref="vert_dst">
  <interpolate axis/>
 </axis>
</grid>
```

- Domain interpolation will be perform first "regular" -> "unstructured"
- Axis interpolation will be perform in 2nd time "vert_src" -> "vert_dst"

Available spatial filters:

LSCE

L Extract

- Extract sub-part of data: extract_axis, extract_domain
- Extract axis to scalar
 - (integer) position: position of the element to be extract from axis.
- Extract axis to axis
 - (integer) n: number of elements to be extract from axis.
 - **(integer)** begin: begin position of the element to be extract from axis.
 - **▶** (1D-array) index: array including all indexes of elements to be extract from axis.
- Extract domain to axis
 - → (string) direction: "iDir" or "jDir"
 - **▶** (integer) position : position of the slice to be extract from domain.
- Extract domain to domain
 - (integer) ni : number of elements to be extract from domain along the i-direction.
 - (integer) nj: number of elements to be extract from domain along the j-direction.
 - → (integer) ibegin: i-position of starting element to be extract from domain.
 - (integer) jbegin: j-position of starting element to be extract from domain.

LSCE

```
<domain id="regular" ni_glo="360" nj_glo="180" type="rectilinear" />
<axis id="axis" n glo="100" />
<grid id="grid_src">
 <domain domain ref="regular"/>
 <axis axis_ref="axis"/>
</grid>
<grid id="grid extract">
 <domain domain_ref="regular">
   <extract domain ni="50" nj="60" ibegin="20" jbegin="100" />
 <domain/>
 <axis axis ref="axis">
   <extract axis begin="30" n="10"/>
 </axis>
</grid>
<field id="field" grid_ref="grid_src"/>
<field id="field extracted" field ref="field" grid ref="grid extract" />
```

- **Extract** data of size (50,60,10) starting at index (20,100,30)
- Only the extracted part will be output to files

Hands-on 7-1

XIOS spatial filter

Available spatial filters:

LSCE

Reduce

Reduce data: reduce_scalar, reduce_axis, reduce_domain

Hands-on 7-3

Reduce scalar to scalar

- **⇒** (string) operation : sum, average, max, min. Perform a MPI_Allreduce
- Reduce axis to scalar
 - **(string) operation**: sum, average, max, min.
- Reduce axis to axis
 - → (string) operation: sum, average, max, min. Perform a MPI_Allreduce
- Reduce domain to scalar
 - **(string) operation**: sum, average, max, min.
 - **♦ (bool) local**: whether the reduction should be performed locally on data owned by each process or on the global domain (default "false")
- Reduce domain to axis
 - → (string) operation: sum, average, max, min.
 - (string) direction : "iDir" or "jDir"
 - ◆ (bool) local: whether the reduction should be performed locally on data owned by each process or on the global domain (default "false")

XIOS spatial filter

🖶 Inverse

inverse_axis

Duplicate

duplicate_scalar : duplicate scalar to axis

Reorder

- reorder_domain
 - **▶** (bool) invert_lat: define whether the latitude should be inverted. (default "false")

 - **▶** (double) max_lon : optional.

 - → If both min_lon and max_lon are defined, domain will be reordered with latitude values ranging from min_lon to max_lon.

∔ Generate domain

- Generate_rectilinear_domain
 - (double) lon_start, lon_end, lat_start, lat_end
 - **▶** (double) bounds_lon_start, bounds_lon_end, bounds_lat_start, bounds_lat_end
 - Range in [0°, 360°] for longitude, [-90°, 90°] for latitude
 - Useful to perform automatic interpolation on regular grid
 - Generate automatically parallel distribution, longitude and latitude values
 - → ni_glo and nj_glo must be defined in the domain element

XIOS spatial filter

Interpolate (only polynomial)

LSCE

- interpolate_domain
 - Perform interpolation between any kind of domain
 - Compute weight on the fly and in parallel at XIOS closing definition step
 - → Interpolation is done on parallel on the incoming distributed flux
 - Current algorithm is only conservative remapping of 1st or 2nd order
 - → (integer) order: set the order (1 or 2) of the conservative interpolation (default "2")
 - ♦ (bool) renormalize: used in case where targeted cells intersect masked source cells. If set to "true", flux is renormalized prorate of the non masked intersected area. (default "false")
 - **| bool | quantity : set to "true" to preserve extensive property of the field (default "false")**
 - ◆ (bool) detect_missing_value : if set to "true" , input data of the field to be interpolated are analyzed to detect missing values. (default "false")
 - ◆ (bool) use_aera: if set to "true", area for source and target domain (if any) will be used to renormalize compute weight by the ratio given area / computed area. Default value is false. Used with domain radius attribute
 - **⇒** (string) mode: "read", "compute", "read_or_compute". This attribute determines the way to obtain interpolation weight information. Default "compute"
 - **| bool) write weight**: set to "true" to write the computed weight to file.
 - **⇒** (string) weight_filename: define the file name where the weights will be written or read. If not specified, when trying to read or write, a name will be automatically generated (contextid_srcdomain_destdomain).
 - **⇒** (string) read_write_convention: index will begin from 0 if set to "c", from 1 if set to "fortran"

Interpolate (only polynomial)

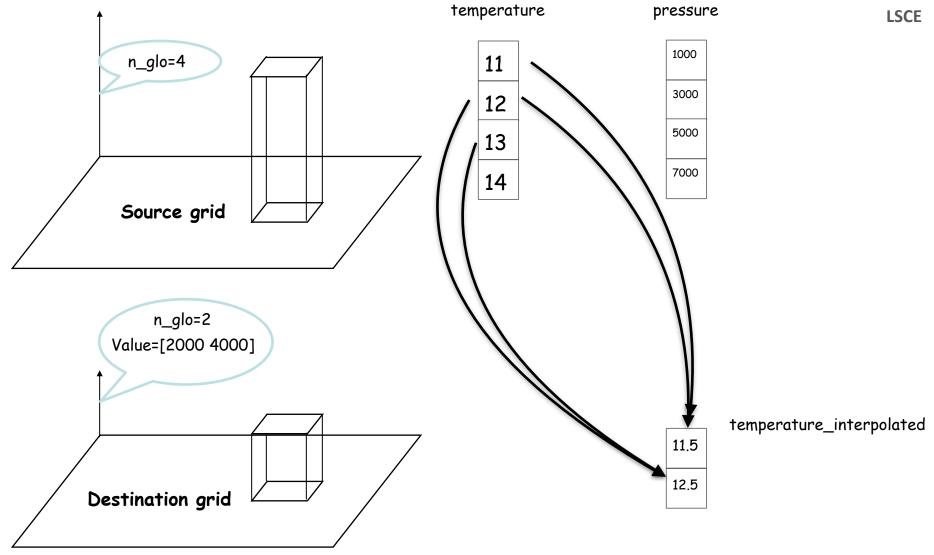

- interpolate_axis
 - **♦** (integer) order: optional. set the order of the polynomial interpolation (default "1")
 - **♦** (string) type : "polynomial" only. Optional
 - → (string) coordinate: defines the coordinate (value) associated with an axis on which interpolation will be performed
 - Apply only on 3D field

∔ Chaining spatial transformation

- Chaining can be easily achieved by referencing intermediate field
 - Ex: interpolate unstructured grid to regular and then make a zoom

- To avoid intermediate field definition, use grid_path attribute

Other possibilities is to chain transformation in domain or axis definition

XIOS temporal splitting filter

🖶 temporal_splitting

LSCE

- This filter generates a data flux which has one extra dimension comparing to the input flux
 - Ex: A 2D field over 4 time steps is transformed into a 3D field with the last dimension of size 4
- To use this filter, you need to at first reshape the input grid: add one scalar element to the grid to increase the grid's dimension

```
<grid id="grid_src">
<domain domain_ref="domain"/>
</grid>
```

```
<grid id="grid_dst_1">
  <domain domain_ref="domain"/>
  <scalar id="scalar"/>
</grid>
```

Source field data can be passed on the new grid using arithmetic operation

```
<field id="field_src" grid_ref="grid_src" />
<field id="field_dst_1" grid_ref="grid_dst_1" > field_src </field>
```

You can then use the temporal splitting filter as other spatial transform filters

```
<grid id="grid_dst_1">
  <domain domain_ref="domain"/>
  <scalar id="scalar"/>
  </grid>
```

```
<grid id="grid_dst">
  <domain domain_ref="domain"/>
  <axis id="axis_ts" n_glo="4">
    <temporal_splitting />
  </axis>
</grid>
```

Hands-on 8

XIOS workflow graph

♣ A good tool for visualize workflow

LJCE

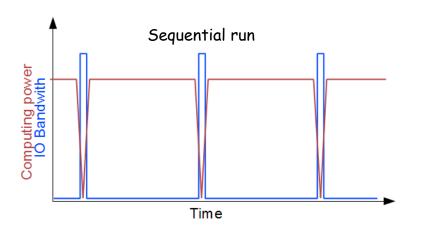

- Field attribute
 - **▶** (bool) build_workflow_graph : set to "true" to enable workflow
- Can be inherited by reference
- https://forge.ipsl.jussieu.fr/ioserver/chrome/site/XIOS_TEST_SUITE/graph.html
- Interactive
- One graph file per context.
 - → graph_data_*.json
- Can be useful for debugging

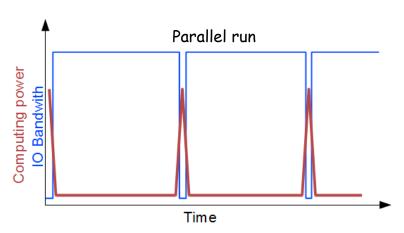

Hands-on 9

- ◆ IO become a big bottleneck in parallel computing up to O(10000) cores
- One file by process?
- Good way to achieve moderate scalability
- → Depending on the file system, performance may break down when attempting to write simultaneously thousand of files
- Files need to be rebuilt into a single file in order to be analysed.
- Rebuilt may take a longer time than the simulations
- Using parallel IO?
- Best way to achieve scalable IO without rebuild file
- ➡ But difficult to aggregate a lot of I/O bandwidth with a big number of writing processes
- Parallel IO is very less scalable than models due to hardware restriction (pricy and not took into account for performance evaluation)

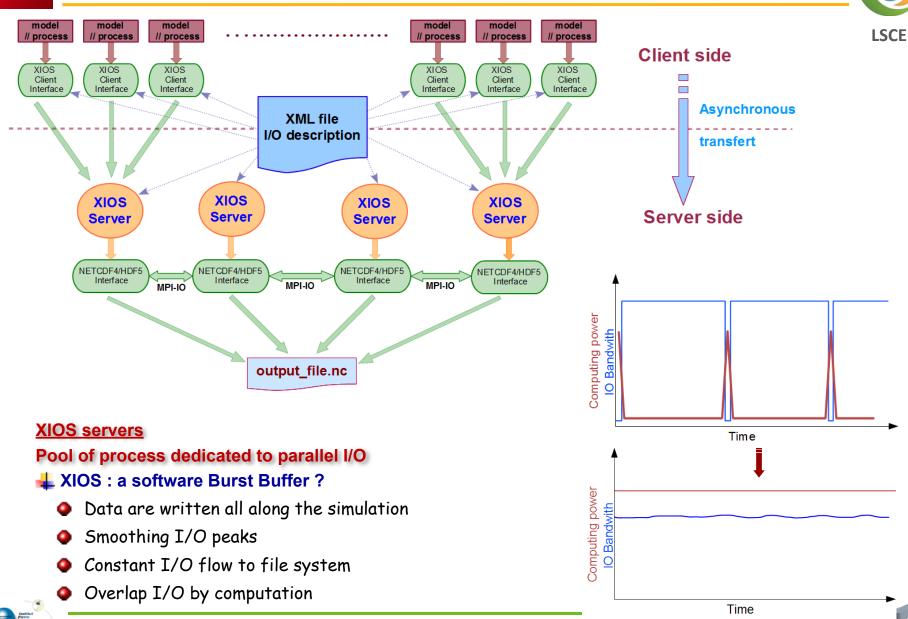

X(ml) IO S(erver)

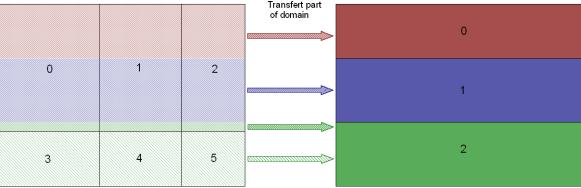

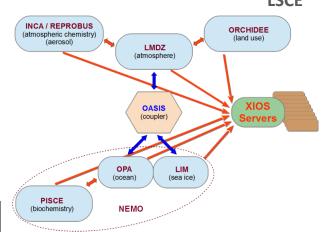

XIOS communication protocol

Complex and fully asynchronous protocol

- One way to send data from clients to servers
- One way to receive data from servers to clients
- ♣ Same pools of I/O servers used in coupled model
- Light side Different data distribution between client and servers

- ∔ Data are sent asynchronously at writing time
 - → Use only MPI point to point asynchronous communication : MPI_Issend, MPI_Irecv, MPI_Test, MPI_Probe...
 - No synchronisation between clients and server, and between servers
 - No latency cost, communications are overlapped by computation
 - Writing is also overlapped by computation
- Late are received asynchronously with prefetching (by advance) on client side

- Large usage of buffers
 - Smoothing I/O peaks
- **▲** Client Side : double buffers
 - Outgoing message in transfer
 - Bufferization of the incoming flow

Client side : double buffer

Pending request

Sent buffer with MPI_Issend Waiting for realease with MPI_Test

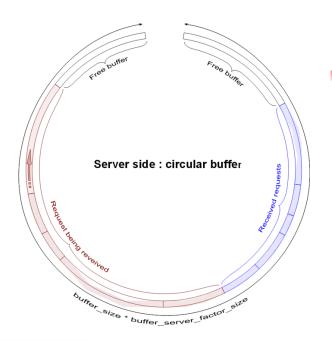

Pending message

Buffered message

Buffer to be sent when pending request is released

Request being buffered

buffer size / 2

L Server Side : circular buffer

Swap buffer rule

alternatively

- Received requests are processed
- In same time than receiving request from client

Overlapping data transfer and I/O by computing

Server mode vs. Attached mode

🖶 Server mode

LSCE

- MPMD mode
 - mpirun -np 1024 model.exe: -np 16 xios_server.exe
- Placing XIOS servers in parallel partition
 - > Strongly hardware dependent
 - ➡ But generally better to spread servers on different computing nodes

Attached mode

- To make development easier XIOS provide an "attach" mode
 - Don't need to launch xios servers executable
 - mpirun -np 12 model.exe
 - XIOS act only as a library
- Each client is itself a server for other clients
 - Pool of servers is equal to the number of clients
- Synchronous
 - Client must wait for the data to be written before continue
- Each client make parallel write
 - performance issue

XIOS 2-level server mode

Why 2-level server?

LSCE

- When number of XIOS servers increases, parallel I/O becomes inefficient due to I/O bandwidth
- Want XIOS servers to work with different output file

🚣 Intermediaries (level one) and writers (level two)

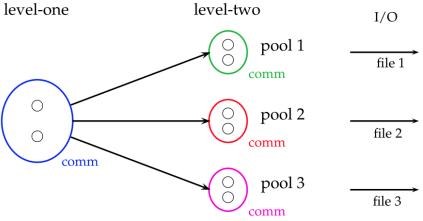

- Level-one servers will receive data from clients, redistribute, and send data to subsets of level-two servers (called "pools")
- Level-two servers will do the I/O

Hands-on 10

- Each file is written by only one pool
- No compression
- But if 1 process is assigned per pool (default option), I/O is then sequential and HDF5 compression can be used
 level true

Parameters: (context id="xios")

- (bool) using server2 : default false
- (integer) ratio_server2 : default 50
- (integer) number_pools_server2 :
- sets the number of server-two pools
- (default is number of second level servers)

XIOS performance report

Performance report

Report is generated at XIOS finalization

Client side: xios_client_00.out

-> report: Performance report: total time spent for XIOS: 32.3497 s

-> report : Performance report : time spent for waiting free buffer : 1.1336 s

-> report : Performance report : Ratio : 3.50421 %

-> report : Performance report : This ratio must be close to zero. Otherwise it may be useful to increase buffer size or numbers of server

Server side: xios server 00.out

-> report : Performance report : Time spent for XIOS : 51.0071

-> report : Performance report : Time spent in processing events : 21.5263

-> report : Performance report : Ratio : 42.2026%

Client side: Time spent for waiting free buffer is small compare to total time

Every thing is OK, no impact of I/O on computing time

Client side: Time spent for waiting free buffer is significant

- Server side: if ratio (time for process event / total time) is close to 100%
 - → I/O throughput is not enough fast to maintains asynchronism
 - Add more servers
- Servers side: if ratio is much less than 100% (60-80%)
 - Servers are not overloaded but cannot absorb and smooth I/O peaks
 - Buffer are to small and need to be increased

XIOS performance report

Memory consumption

- XIOS consumes memory internally
- XIOS uses large transfer buffer
- Part of memory is consumed by NETCDF4/HDF5
- But generally, memory consumption is scalable (client & server)
- Information about memory usage
- Buffer size is automatically computed
 - Can be different for each communication channel (client-server couple)
 - Dependent of the parallel data distribution
- 2 buffers for each client-server couple
 - → 1 for sending data from client to server (I/O write)
 - → 1 for receiving data from server to client (I/O read)

Client side: xios_client_00.out

- -> report : Memory report : Context <atmosphere> : client side : total memory used for buffer 2932872 bytes
- -> report : Memory report : Context <atmosphere> : server side : total memory used for buffer 209733 bytes
- -> report : Memory report : Minimum buffer size required : 209730 bytes
- -> report : Memory report : increasing it by a factor will increase performance, depending of the volume of data wrote in file at each time step of the file

Server side: xios_server_00.out

- -> report : Memory report : Context <atmosphere_server> : client side : total memory used for buffer 209733 bytes
- -> report : Memory report : Context <atmosphere_server> : server side : total memory used for buffer 1710664 bytes

🖶 Managing buffer size

- Buffer sizes are automatically computed
- User can choose between 2 behaviors (parameter optimal_buffer_size):
- Buffer sizes optimized for memory
 - → Size adjusted to the biggest transfer
 - Minimal memory consumption for buffer
 - But losing most part of asynchronous transfer
- Buffer sizes optimized for performance
 - Sizes are adjusted to bufferize all data between two output period
 - Fully asynchronous
- User can adjust size by itself using a multiplying factor
 - **♦** (double) buffer_size_factor

XIOS parametrization

- (string) optimal buffer size : specify buffer sizing behavior (default : "performance")
 - "performance" or "memory"
- (double) buffer size factor: multiplying the computed buffer size by this factor
 - Use with caution
- (integer) min_buffer_size : fix the minimum size of buffers
 - Use only in case of bad computed size
 - Can help to workaround an unexpected problem
- (boolean) using server: specify "server mode" or "attached mode"
 - > XIOS try to determine itself the chosen mode by analyzing MPI communicator
 - Useful only for coupled model configuration
- (integer) info_level: level of xios information output (0-100), 0 nothing, 100 full, (default=0)
- (boolean) print file: if true, xios standard output and error are redirected in files indexed by process rank, (default=false)
- (boolean) xios_stack : if true, you will get a full error traceback (default=true)

Hands-on 11

XIOS parametrization

XIOS context is used for parametrization

- Specific XIOS context in XML file
- Used only for reading variable value
- Actually, all parameters are optional, just override default value

```
<context id="xios">
    <variable_definition>

    <variable id="optimal_buffer_size" type="string">performance</variable>
         <variable id="buffer_size_factor" type="double">1.0</variable>
         <variable id="min_buffer_size" type="int">100000</variable>
         <variable id="using_server" type="bool">false</variable>
         <variable id="using_oasis" type="bool">false</variable>
         <variable id="info_level" type="int">50</variable>
         <variable id="print_file" type="bool">true</variable>
         </variable_definition>
         </context>
```

In the past CMIP6 ...

- Configuration : model IPSLCM6-LR
 - Atmosphere : 144x143x79 (2°, 79 vertical levels)
 - Ocean : ORCA1, L75 (1°, 75 vertical levels)
 - Performances: 16 SYPD on 930 cores on Curie (Bull, intel Sandy-Bridge)
- CMIP6 light I/O throughput (piControl, large part of the CMIP6 runs)
 - Config: 1 years (1850) piControl: 4 XIOS servers
 - No I/O: 4980 s
 - Only IO Standard : 5460s (+10%)
 - Only CMIP6 I/O: 5460 s (+10%, 0% compared to standard I/O)
 - CMIP6 + standard : 5820 s (+16%, +6% compared to only standard I/O)
- CMIP6 medium I/O throughput: 1 year historical 1850, CMIP6 I/O + standard
 - 927 files / variables, 158 Gb (compressed)
 - 12 XIOS servers
 - CMIP6 + standard : 6454 s (+18 % compared to only standard I/O)

- CMIP 6 High I/O throughput : one year Full CMIP6 I/O output + standard I/O
 - 1173 files/variables, 1.5 Tb (compressed)

config	time	% Vs standard I/O
4 XIOS -2 NODES	16440 s	+201 %
8 XIOS - 4 NODES	13020 s	+138 %
16 XIOS - 2 NODES	9300 s	+70 %
16 XIOS - 4 NODES	9600 s	+75 %
16 XIOS - 8 NODES	9360 s	+71 %
24 XIOS - 2 NODES	8460 s	+54 %
24 XIOS - 8 NODES	8040 s	+47 %
24 XIOS - 12 NODES	7860 s	+44 %
32 XIOS - 2 NODES	8460 s	+55 %

- Non negligible impact on computing time: +44 %
- Impact come from workflow cost, not I/O
- But for a low number of runs (<5%), so it remains acceptable
