

A plea for parameter traceability

Based on discussions and shared frustrations with: Juliane Otto, James Ryder, Yi-Ying Chen, Kim Naudts, Aude Valade, Jonathan Barichivich, Natasha MacBean, Anne Sofie Lanso, Guillaume Marie, Matthew McGrath, Jina Jeong, Philippe Peylin & Sebastiaan Luysaert

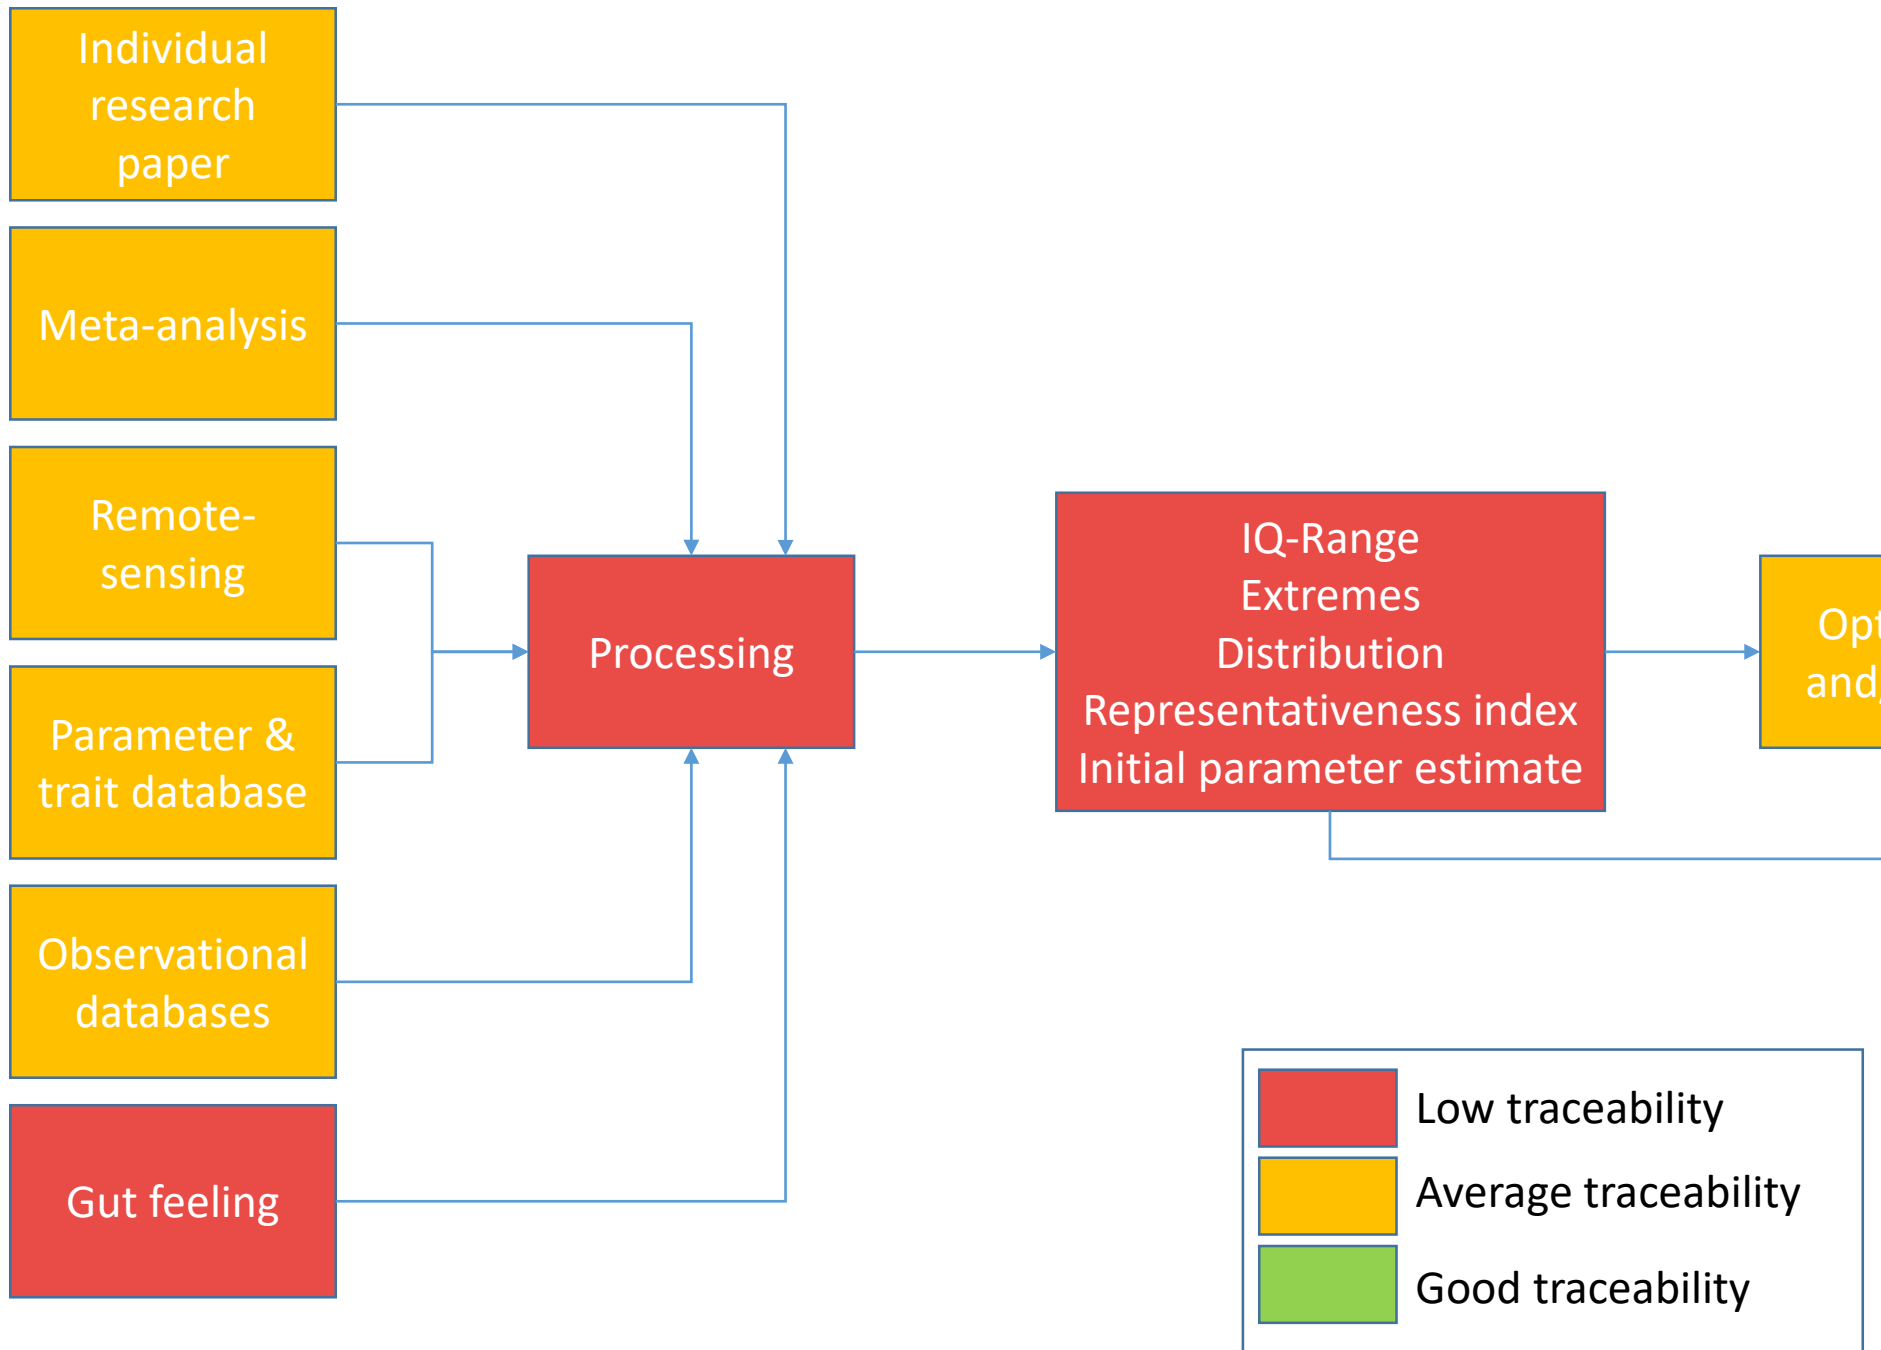

Where do we get the model parameters from?

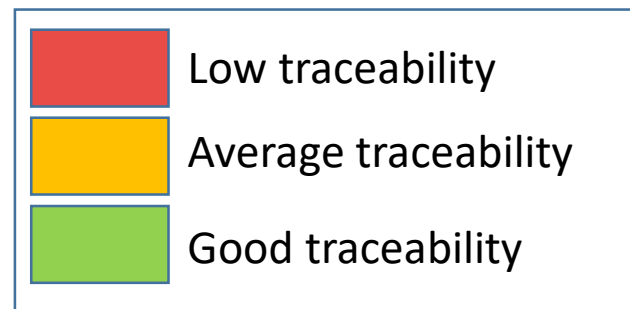

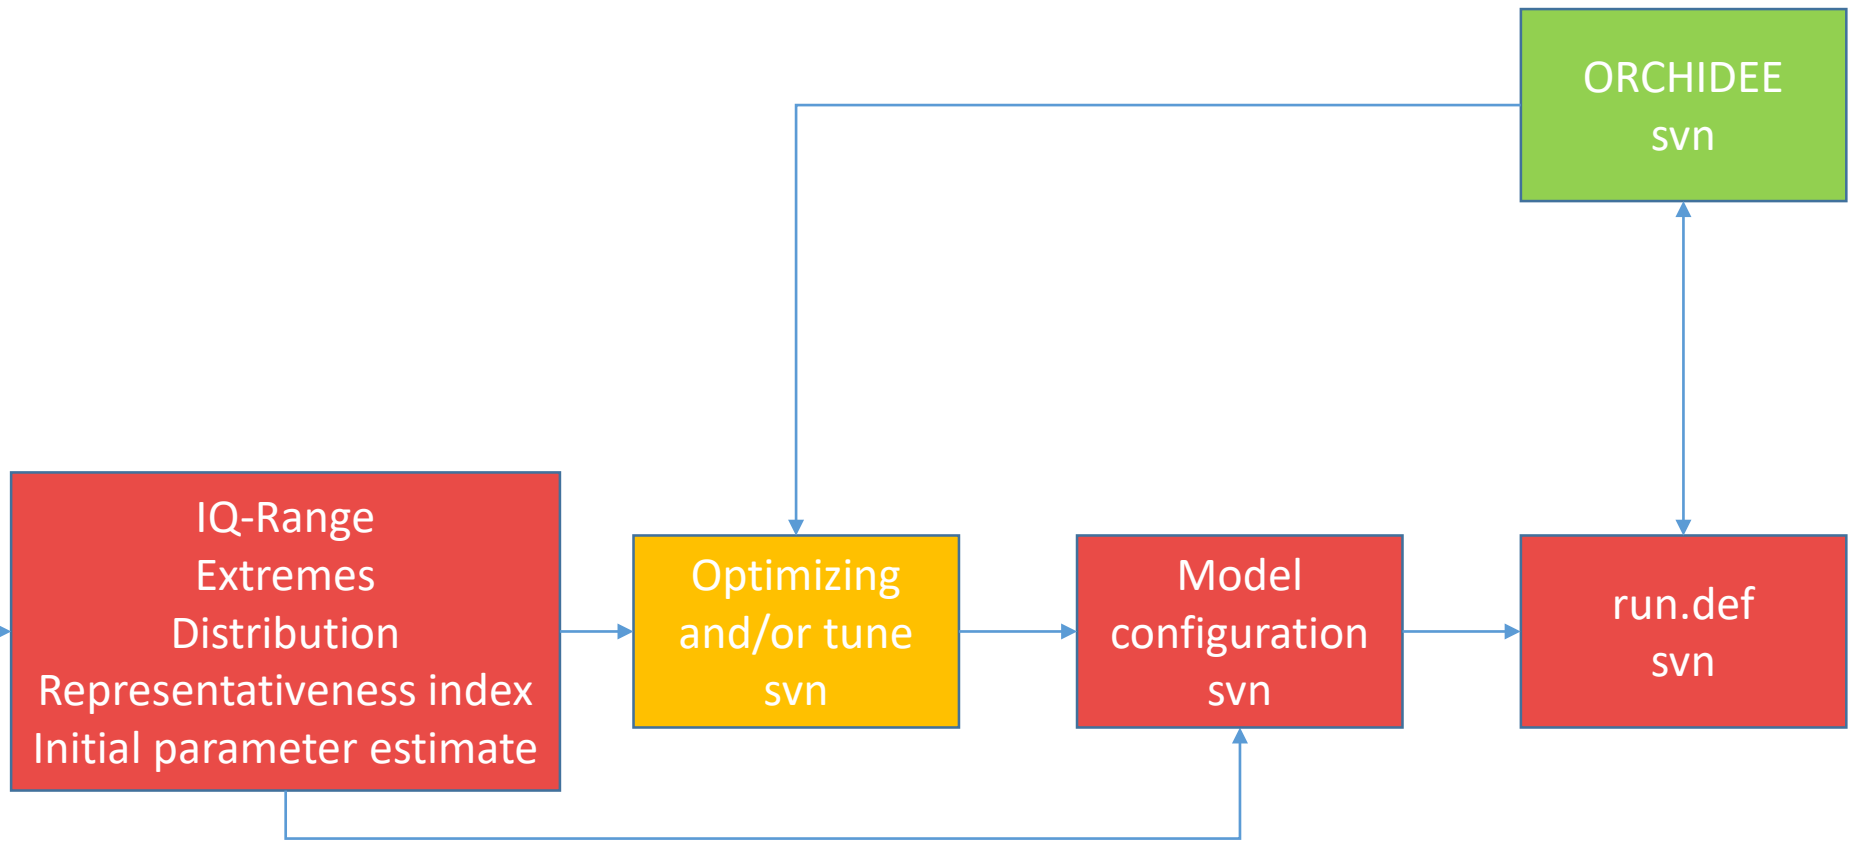

What makes us use a specific parameter value?

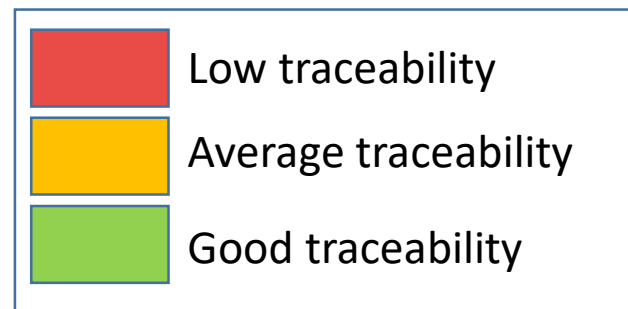

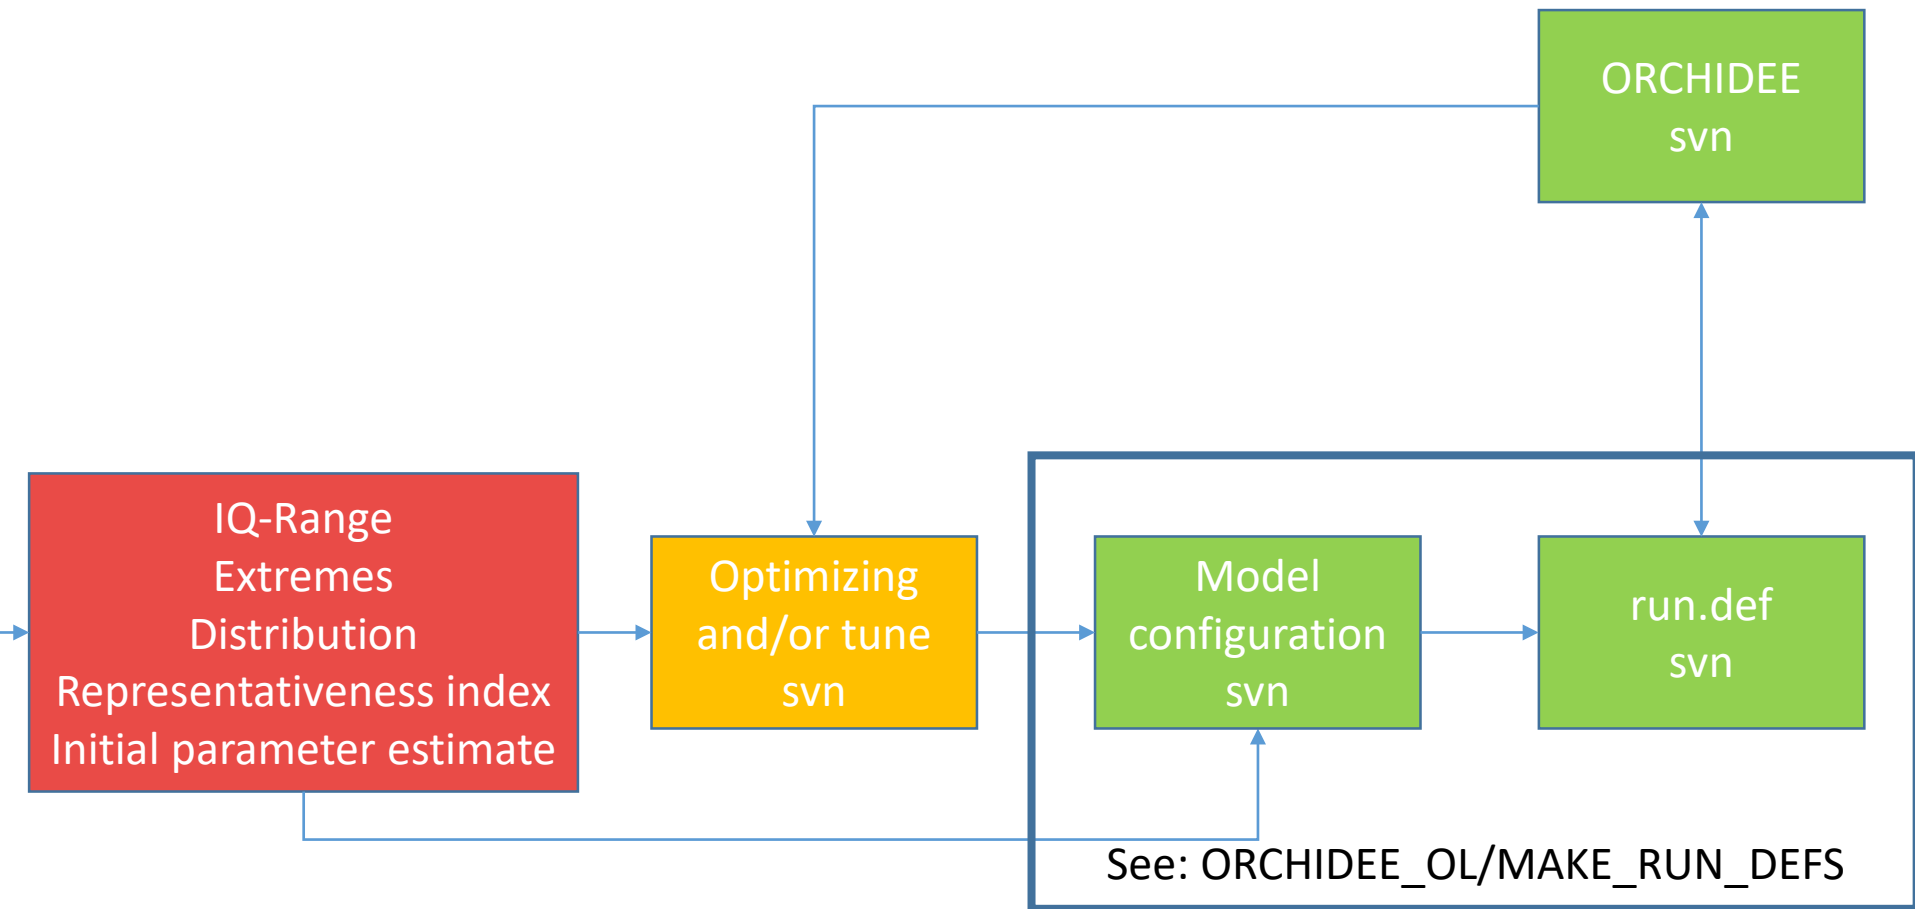

Why was the value changed from one model version to another?

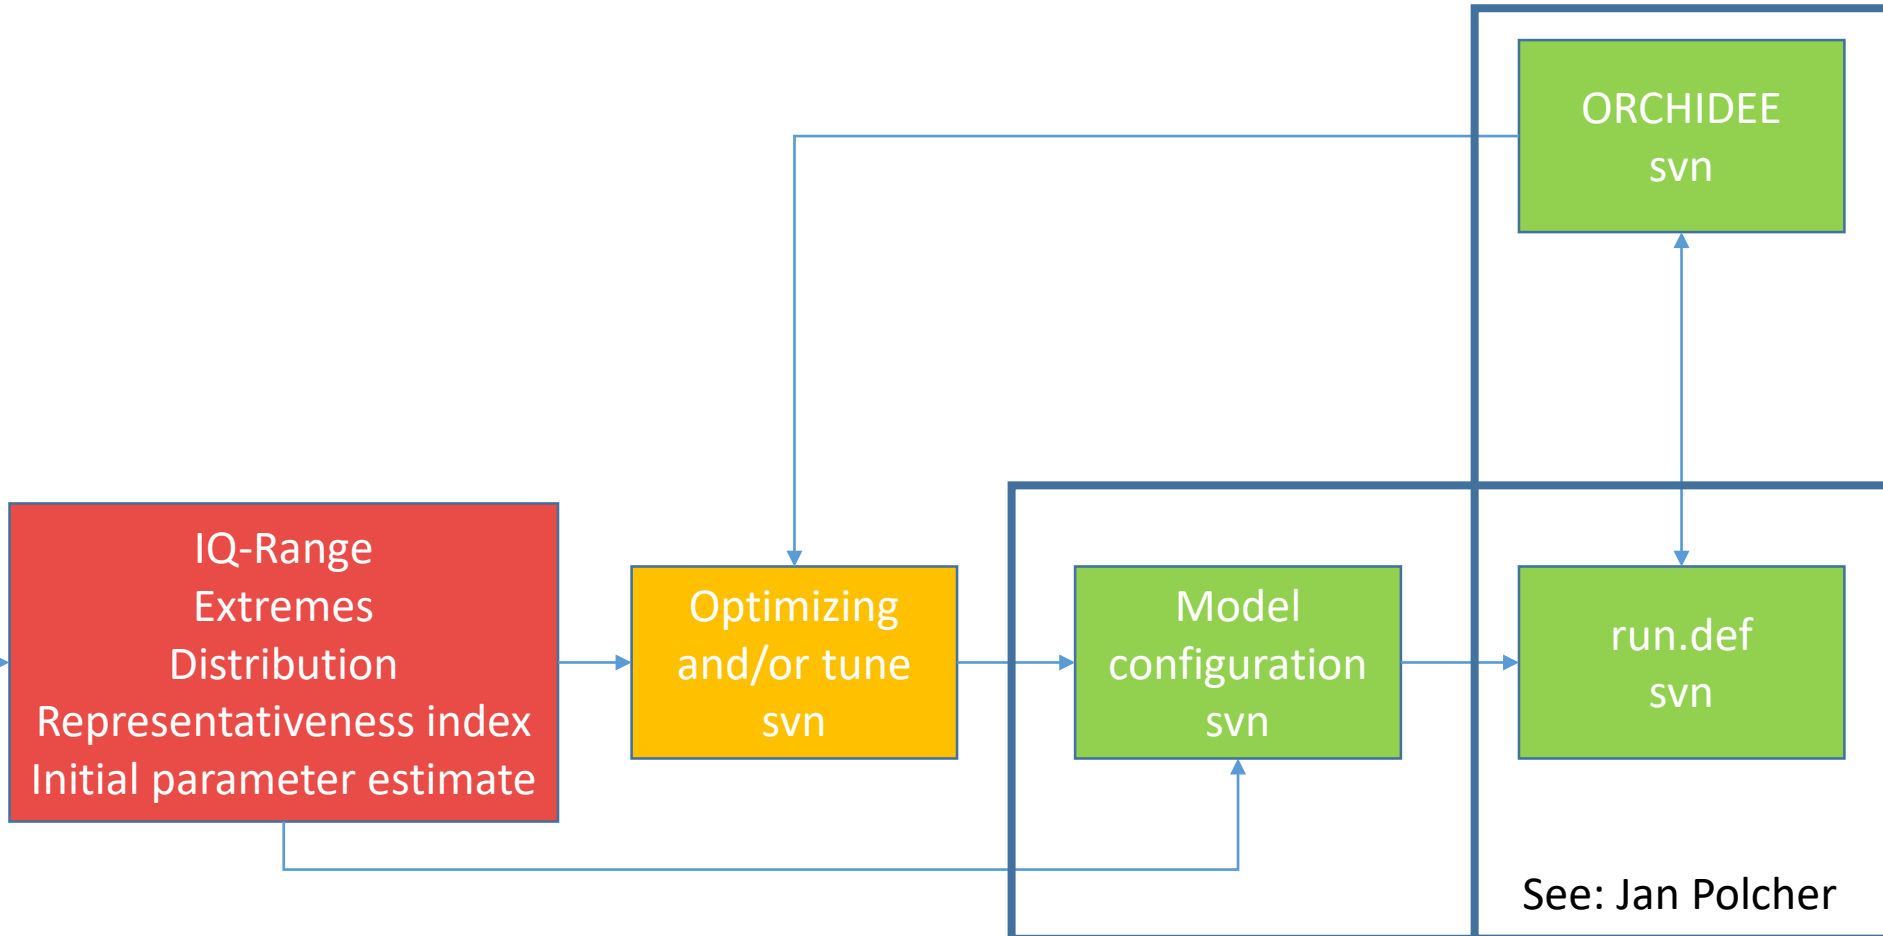

Which parameter values were used in specific publications?

Which parameter values were used in specific MIPs?

	Low traceability
	Average traceability
	Good traceability

THROUGHFALL

ECOLOGY -> MOST of the OBSERVATIONS

Throughfall = 70%

Stemflow = 10%

Interception = 20%

Calculating throughfall from prescribed parameters

$\text{Precipsol} = (\text{throughfall} + \text{stemflow}) * \text{precipitation}$

$\text{Vevapwet} = (1 - \text{throughfall} - \text{stemflow}) * \text{precipitation}$

ORCHIDEE:

Calculating throughfall as a function of the canopy structure -> no need to prescribe it

(1) No interaction with the canopy (passing through the gaps) -> $(\text{veget_max} - \text{veget}) * \text{precip}$

(2) Interacts with the canopy -> $\text{veget} * \text{precip}$

(3) Interception -> vevapwet

(4) $\text{Precipsol} = (1) + (2) - (3)$; depending on sign convention)
