

The surface-atmosphere interactions

COUPLING BETWEEN ATMOSPHERE AND SURFACE

Processes involved

Photo by: Jay Chapman / Flickr

Photo by: Jay Chapman / Flickr

The **atmosphere and the surface are coupled** through *turbulence* (in boundary layer) and *radiation* (SW and LW).

Surface impacts atmosphere via orography, roughness, albedo, emissivity

Atmosphere-surface interactions in IPSL-CM

In LMDZ:

Each surface grid can be decomposed in a maximum of 4 sub-grid of different type: land (_ter), continental ice (_lic), open ocean (_oce) and sea_ice (_sic)

Radiation at the surface depends on mean surface properties (albedo, emissivity)

Turbulent diffusion depends on local sub-grid properties but each sub-surface sees the same atmosphere

 Agrégation de flux mailles mixtes (océan, continents, sea-ice,...)

Solving the tridiagonal system

X= wind, enthalpy, specific humidity, tracers

Case of the continental surface

$$\left\{ \begin{array}{l} F_{s,H}^t = A_H^1 + B_H^1 F_{s,H}^t \delta t \quad \text{Turbulent diffusion Atmosphere} \\ F_{s,H}^t = \frac{1}{zik t} (H_1^t - H_s^t) \quad \frac{1}{zik t} = \rho |\vec{v}| C_d \quad \text{Bulk formulation} \end{array} \right.$$

$$F_{s,H}^t = \frac{1}{zik t} (A_H^1 + B_H^1 \cdot F_{s,H}^t \delta t - H_s^t)$$

$$F_{s,H}^t = \frac{1}{zik t} \left[\frac{(A_H^1 - H_s^{t-\delta t})}{1 - \frac{1}{zik t} B_H^1 \delta t} - \frac{(H_s^t - H_s^{t-\delta t})}{1 - \frac{1}{zik t} B_H^1 \delta t} \right]$$

C_d^x drag coefficient (Monin Obukhov, constant f
in the surface layer)

depends on

- roughness lengths (gustiness, vegetation), orography
- Richardson number (boundary layer stability)
- Formulation depends on the sub-surface type

$$F_{s,H}^t = sens fl_{old} - sens fl_{sns} (T_s^t - T_s^{t-\delta t})$$

- Top boundary condition:

Continuity of the fluxes and the temperature between sub-surface and atmosphere

$$C' * \frac{T_s^t - T_s^0}{\delta t} = G' * + SW_{\text{net}} + LW_d + \sum F^\downarrow(T_s^t) - \varepsilon \sigma (T_s^t)^4$$

Solved using the sensitivity of the flux to the surface temperature to calculate the flux at the new time-step

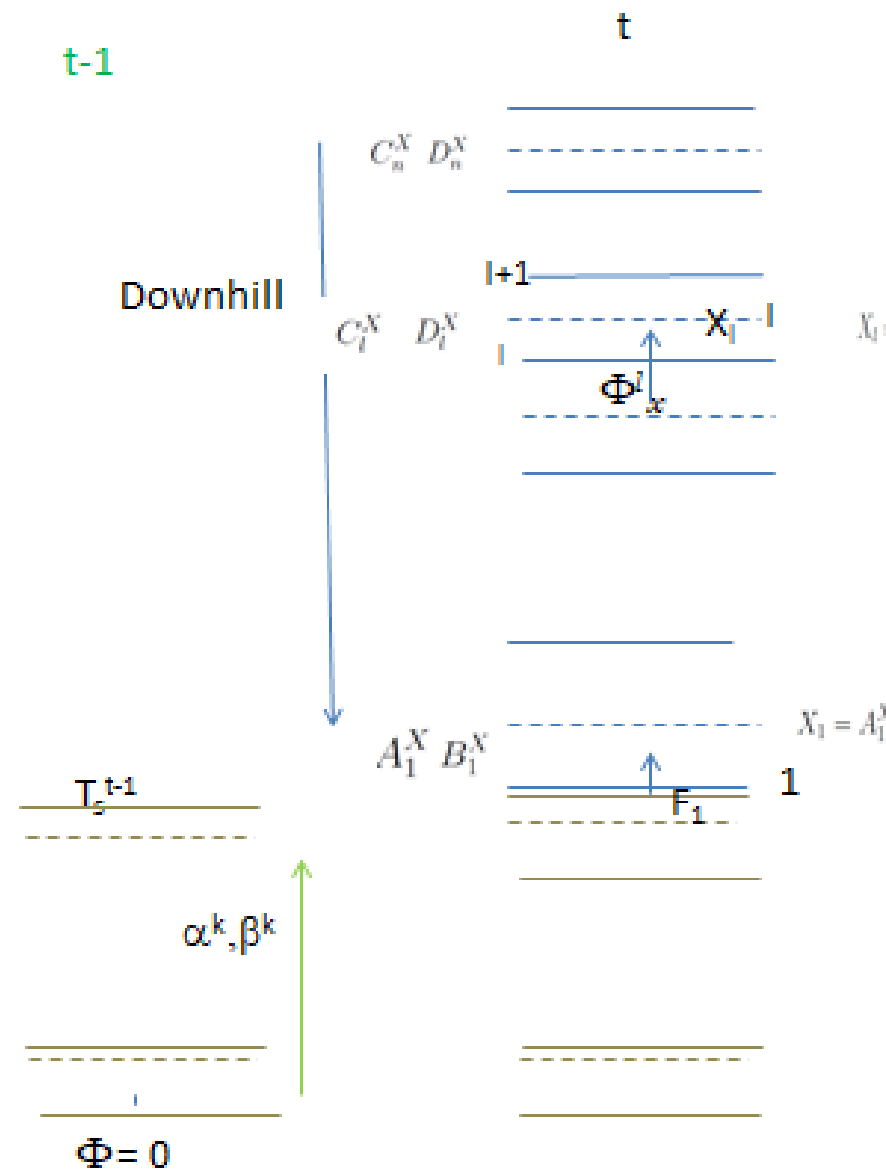

$$F_{s,H}^t = \text{sensfl}_{\text{old}} - \text{sensfl}_{\text{sns}}(T_s^t - T_s^{t-\delta t})$$

$$\sigma * T_s^{t-\delta t^4} - 4\varepsilon \sigma T_s^{t-\delta t^3} (T_s^t - T_s^{t-\delta t})$$

$$T_s^t = f(SW_{\text{net}} + LW_d, T_s^0, F_s^0)$$

In LMDZ
 climb_hq_down
 and
 climb_wind_down

At t α_k and β_k depend on T_k at
 the previous time step and on
 the underlying layers:
 They can be pre-computed

Coupling between atmospheric column(s) and sub-surfaces

Each grid cell is divided into several sub-areas or "sub-surfaces" of fractions ω_i

Sub-surfaces

$$\sum_i \omega_i = 1$$

Turbulent
flux

One PBL over **each**
sub-surface

Radiative
flux

One column
covers all the sub-
surface

Each sub surface has to compute F_1 using variables X_p , A_1 and B_1

The boundary layer tendencies in the atmosphere are mixed between sub-columns (equivalent of averaging the surface flux)

Derivation of local sub-surface **net solar radiation** from grid average net solar radiation

The grid average net flux Ψ_s at surface has been computed for each grid point by the radiative code

We want (1) to conserve energy and (2) to take into account the value of the local albedo α_i of the sub-surface.

We compute the downward SW radiation as
$$F_{\downarrow}^s = \frac{\Psi_s}{(1 - \alpha)}$$

with the mean albedo
$$\alpha = \sum_i \omega_i \alpha_i$$

$$\psi_i^s = (1 - \alpha_i) F_{\downarrow}^s$$

For each sub-surface i, the absorbed solar radiation reads:

$$\psi_i^s = \frac{(1 - \alpha_i)}{(1 - \alpha)} \bar{\Psi}_s$$

One may verify that this procedure ensure energy conservation, i.e.
$$\sum_i \omega_i \psi_i^s = \Psi_s$$

Derivation of local sub-surface **net longwave radiation** from grid average net longwave radiation

The net longwave (LW) radiation $\bar{\Psi}^L$ has been computed by the radiative code for each grid cell. How to split it depending on the sub-surfaces local properties and ensuring energy conservation?

If the downward longwave flux F_{\downarrow} is uniform within each grid, the net LW flux for a sub-surface i may be written as:

$$\psi_i^L(T_i) = \epsilon_i (F_{\downarrow} - \sigma T_i^4) \quad (1)$$

where T_i is the surface temperature of sub-surface i and ϵ_i its emissivity. A linearization around the mean temperature \bar{T} gives:

$$\psi_i^L(T_i) \approx \epsilon_i (F_{\downarrow} - \sigma \bar{T}^4) - 4\epsilon_i \sigma \bar{T}^3 (T_i - \bar{T}) \quad (2)$$

To conserve the energy, the following relationship must be true:

$$\sum_i \omega_i \psi_i^L = \bar{\Psi}^L \quad (3)$$

Using Eq. 2 gives

$$\sum_i \omega_i \psi_i^L = \bar{\epsilon} (F_{\downarrow} - \sigma \bar{T}^4) - 4\sigma \bar{T}^3 \sum_i \omega_i \epsilon_i (T_i - \bar{T}) \quad (4)$$

where $\bar{\epsilon} = \sum_i \omega_i \epsilon_i$ is the mean emissivity.

Derivation of local sub-surface **net longwave radiation** from grid average net longwave radiation

$$\sum_i \omega_i \psi_i^L = \bar{\epsilon} (F_{\downarrow} - \sigma \bar{T}^4) - 4\sigma \bar{T}^3 \sum_i \omega_i \epsilon_i (T_i - \bar{T}) \quad (4)$$

where $\bar{\epsilon} = \sum_i \omega_i \epsilon_i$ is the mean emissivity. The second term on the right hand side is zero if

$$\bar{T} = \frac{\sum_i \omega_i \epsilon_i T_i}{\bar{\epsilon}} \quad (5)$$

To ensure energy conservation, we need in addition to verify:

$$\bar{\Psi}^L = \bar{\epsilon} (F_{\downarrow} - \sigma \bar{T}^4) \quad (6)$$

Which is consistent with the definition of the net LW flux at the surface. We rewrite now Eq. 2 as:

$$\psi_i^L(T_i) \approx \frac{\epsilon_i}{\bar{\epsilon}} \bar{\Psi}^L - 4\epsilon_i \sigma \bar{T}^3 (T_i - \bar{T}) \quad (7)$$

Due to radiative code limitation, in LMDZ, we always must have $\epsilon_i = 1$
Energy conservation: the radiation is computed by the atmospheric model,
